

Automotive low dropout voltage regulator

Datasheet - production data

very low output current mode and enabled regulator. The devices drop to 6 μA with not enabled regulators.

On chip trimming results in high output voltage accuracy ($\pm 2\%$). Accuracy is kept over wide temperature range, line and load variation.

The maximum input voltage is 40 V. The max. output current is internally limited. Internal temperature protection disables the voltage regulator output.

Features

- AEC-Q100 qualified
- Operating DC supply voltage range 5.6 V to 31 V
- Low quiescent current (6 μA typ. at 25 °C with enable low)
- High precision output voltage ($\pm 2\%$)
- Low dropout voltage less than 0.5 V
- Reset circuit sensing the output voltage down to 1 V
- Programmable reset pulse delay with external capacitor
- Watchdog
- Programmable watchdog timer with external capacitor
- Thermal shutdown and short-circuit protection
- Automotive temperature range ($T_j = -40\text{ °C}$ to 150 °C)
- Enable input for enabling/disabling the voltage regulator output

2 Electrical specifications

2.1 Absolute maximum ratings

Stressing the device above the ratings listed in [Table 3](#) may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to the conditions reported in this section for extended periods may affect device reliability. Refer also to the STMicroelectronics SURE program and other relevant quality documents.

Table 3. Absolute maximum ratings

Symbol	Parameter	Value	Unit
V_{vsdc}	DC supply voltage	-0.3 to 40	V
I_{vsdc}	Input current	Internally limited	
V_{vo}	DC output voltage	-0.3 to 6 ⁽¹⁾	V
I_{vo}	DC output current	Internally limited	
V_{wi}	Watchdog input voltage	-0.3 to $V_{vo} + 0.3$	V
V_{od}	Open drain output voltage (RES)	-0.3 to $V_{vo} + 0.3$	V
I_{od}	Open drain output current (RES)	Internally limited	
V_{cr}	Reset delay voltage	-0.3 to $V_{vo} + 0.3$	V
V_{cw}	Watchdog delay voltage	-0.3 to $V_{vo} + 0.3$	V

3 Application information

3.1 Voltage regulator

The voltage regulator uses a p-channel MOS transistor as a regulating element. With this structure, a low dropout voltage at current up to 150 mA is achieved. The output voltage is regulated up to a transient input supply voltage of 40 V. No functional interruption due to overvoltage pulses is generated. The high precision of the output voltage is obtained with a pretrimmed reference voltage. A short-circuit protection to GND is provided.

Figure 3. Behavior of output current versus regulated voltage V_o

3.2 Reset

The reset circuit monitors the output voltage V_o . If the output voltage drops below V_{o_th} then R_{es} becomes low with a delay time t_{rr} . Real t_{rr} value changes as a non-linear function of delta ($V_{o_th} - V_o$). The reset low signal is guaranteed for an output voltage V_o greater than 1 V.

When the output voltage becomes higher than V_{o_th} then R_{es} goes high with a delay t_{rd} . This delay is obtained by 512 periods of an oscillator (see fig. 5). The oscillator period is given by:

$$T_{OSC} = \frac{[(V_{rhth} - V_{rlth}) \cdot C_{tr}]}{I_{cr}} + \frac{[(V_{rhth} - V_{rlth}) \cdot C_{tr}]}{I_{dr}}$$

and reset pulse delay t_{rd} is given by:

$$t_{rd} = 512 \times T_{OSC}$$

Table 10. Reset time diagram

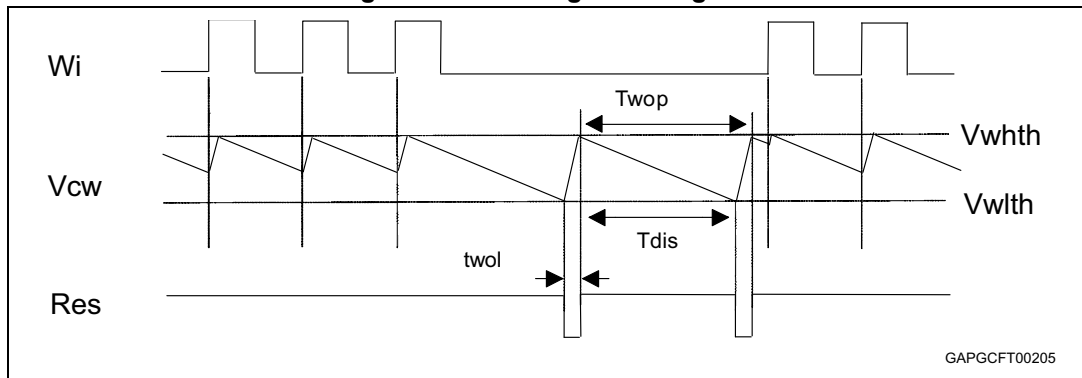

3.3 Watchdog

The watchdog input W_i monitors a connected microcontroller. If pulses are missing, the reset output R_{es} is set to low. The pulse sequence time can be set within a wide range through the external capacitor C_{tw} . The watchdog circuit discharges the capacitor C_{tw} with the constant current I_{cwd} . If the lower threshold V_{wlth} is reached, a watchdog reset is generated. To prevent this reset, the microcontroller must generate a positive edge during the discharge of the capacitor before the voltage has reached the threshold V_{wlth} . In order to calculate the minimum time T_{dis} during which the microcontroller must generate the positive edge, the following equation can be used:

$$(V_{whth} - V_{wlth}) \times C_{tw} = I_{cwd} \times T_{dis}$$

Each W_i positive edge switches the current source from discharging to charging; the same happens when the lower V_{wlth} threshold is reached. When the voltage reaches the upper threshold V_{whth} the current switches from charging to discharging. The result is a saw tooth voltage at the watchdog timer capacitor C_{tw} .
