RM0487
Reference manual

STM32U3 series Arm®-based 32-bit MCUs

Introduction

This reference manual complements the datasheets of the STM32U3 series microcontrollers, providing information required for application and in particular for software development. It pertains to the superset of feature sets available on STM32U3 series microcontrollers.

For feature set, ordering information, and mechanical and electrical characteristics of a particular STM32U3 series device, refer to its corresponding datasheet.

For information on the Arm® Cortex-M33 core, refer to the *Cortex-M33 technical reference manual*.

The STM32U3 series microcontrollers include ST state-of-the-art patented technology.

1 Documentation conventions 87

1.1 General information 87

1.2 List of abbreviations for registers 87

1.3 Register reset value 87

1.4 Glossary 88

1.5 Availability of peripherals 88

2 Memory and bus architecture 89

2.1 System architecture 89

2.1.1 Fast C-bus 90

2.1.2 Slow C-bus 90

2.1.3 S-bus 90

2.1.4 GPDMA-bus 91

2.1.5 SDMMC1 controller DMA bus 91

2.1.6 Bus matrix 91

2.1.7 AHB/APB bridges 91

2.2 Arm TrustZone security architecture 91

2.2.1 Default Arm TrustZone security state 92

2.2.2 Arm TrustZone peripheral classification 93

2.3 Memory organization 97

2.3.1 Introduction 97

2.3.2 Memory map and register boundary addresses 98

2.3.3 Embedded SRAMs 102

2.3.4 Flash memory overview 103

3 System security 104

3.1 Key security features 104

3.2 Secure install 105

3.3 Secure boot 105

3.3.1 Unique boot entry and BOOT_LOCK 106

3.3.2 Immutable root of trust in system flash memory 106

3.4 Secure update 106

3.5 Resource isolation using TrustZone 107

3.5.1 TrustZone security architecture . . . 107
3.5.2 Armv8-M security extension of Cortex-M33 . . . 108
3.5.3 Memory and peripheral allocation using IDAU/SAU . . . 108
3.5.4 Memory and peripheral allocation using GTZC . . . 110
3.5.5 Managing security in TrustZone-aware peripherals . . . 113
3.5.6 Activating TrustZone security . . . 120
3.5.7 Deactivating TrustZone security . . . 121
3.6 Other resource isolations . . . 121
3.6.1 Temporal isolation using secure hide protection (HDP) . . . 121
3.6.2 Resource isolation using Cortex privileged mode . . . 122
3.7 Secure execution . . . 125
3.7.1 Memory protection unit (MPU) . . . 126
3.7.2 Embedded flash memory write protection . . . 126
3.7.3 Tamper detection and response . . . 126
3.8 Secure storage . . . 127
3.8.1 Hardware secret key management . . . 128
3.8.2 Unique ID . . . 129
3.9 Cryptographic engines . . . 129
3.9.1 Cryptographic engines features . . . 129
3.9.2 Secure AES co-processor (SAES) . . . 130
3.10 Product life-cycle . . . 131
3.10.1 Life-cycle management with readout protection (RDP) . . . 132
3.10.2 Recommended option-byte settings . . . 134
3.11 Access controlled debug . . . 135
3.11.1 Debug protection with readout protection (RDP) . . . 135
3.12 Software intellectual property protection and collaborative development 135
3.12.1 Software intellectual property protection with RDP . . . 136
3.12.2 Other software intellectual property protections . . . 137

4 Boot modes . . . 138
4.1 Embedded bootloader . . . 140
4.2 Embedded root security services (RSS) . . . 140

5 Global TrustZone controller (GTZC) . . . 141
5.0.1 GTZC introduction . . . 141
5.0.2 GTZC main features . . . 141

5.0.3 GTZC implementation . . . 143
5.1 GTZC functional description . . . 144
5.1.1 GTZC block diagram . . . 144
5.1.2 Illegal access definition . . . 145
5.1.3 TrustZone security controller (TZSC) . . . 146
5.1.4 Memory protection controller - block based (MPCBB) . . . 146
5.1.5 TrustZone illegal access controller (TZIC) . . . 146
5.1.6 Power-on/reset state . . . 147
5.1.7 GTZC interrupts . . . 147
5.2 GTZC1 TZSC registers . . . 147
5.2.1 GTZC1 TZSC control register (GTZC1_TZSC_CR) . . . 147
5.2.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1) . . . 148
5.2.3 GTZC1 TZSC secure configuration register 2 (GTZC1_TZSC_SECCFGR2) . . . 150
5.2.4 GTZC1 TZSC secure configuration register 3 (GTZC1_TZSC_SECCFGR3) . . . 152
5.2.5 GTZC1 TZSC privilege configuration register 1 (GTZC1_TZSC_PRIVCFGR1) . . . 154
5.2.6 GTZC1 TZSC privilege configuration register 2 (GTZC1_TZSC_PRIVCFGR2) . . . 156
5.2.7 GTZC1 TZSC privilege configuration register 3 (GTZC1_TZSC_PRIVCFGR3) . . . 157
5.2.8 GTZC1 TZSC register map . . . 159
5.3 GTZC1 TZIC registers . . . 160
5.3.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1) . . . 160
5.3.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2) . . . 162
5.3.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3) . . . 163
5.3.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4) . . . 165
5.3.5 GTZC1 TZIC status register 1 (GTZC1_TZIC_SR1) . . . 166
5.3.6 GTZC1 TZIC status register 2 (GTZC1_TZIC_SR2) . . . 168
5.3.7 GTZC1 TZIC status register 3 (GTZC1_TZIC_SR3) . . . 170
5.3.8 GTZC1 TZIC status register 4 (GTZC1_TZIC_SR4) . . . 171
5.3.9 GTZC1 TZIC flag clear register 1 (GTZC1_TZIC_FCR1) . . . 173
5.3.10 GTZC1 TZIC flag clear register 2 (GTZC1_TZIC_FCR2) . . . 175
5.3.11 GTZC1 TZIC flag clear register 3 (GTZC1_TZIC_FCR3) . . . 176
5.3.12 GTZC1 TZIC flag clear register 4 (GTZC1_TZIC_FCR4) . . . 178
5.3.13 GTZC1 TZIC register map . . . 179

5.4 GTZC1 MPCBB1 registers 181
5.4.1 GTZC1 SRAM1 MPCBB control register (GTZC1_MPCBB1_CR) . . . 181
5.4.2 GTZC1 SRAM1 MPCBB configuration lock register 1 (GTZC1_MPCBB1_CFGLOCKR1) 182
5.4.3 GTZC1 SRAM1 MPCBB security configuration for super-block x register (GTZC1_MPCBB1_SECCFGRx) 182
5.4.4 GTZC1 SRAM1 MPCBB privileged configuration for super-block x register (GTZC1_MPCBB1_PRIVCFGRx) 183
5.4.5 GTZC1 MPCBB1 register map 183
5.5 GTZC1 MPCBB2 registers 184
5.5.1 GTZC1 SRAM2 MPCBB control register (GTZC1_MPCBB2_CR) . . . 184
5.5.2 GTZC1 SRAM2 MPCBB configuration lock register 1 (GTZC1_MPCBB2_CFGLOCKR1) 185
5.5.3 GTZC1 SRAM2 MPCBB security configuration for super-block x register (GTZC1_MPCBB2_SECCFGRx) 185
5.5.4 GTZC1 SRAM2 MPCBB privileged configuration for super-block x register (GTZC1_MPCBB2_PRIVCFGRx) 186
5.5.5 GTZC1 MPCBB2 register map 186

6 RAM configuration controller (RAMCFG) 187
6.1 RAMCFG introduction 187
6.2 RAMCFG main features 187
6.3 RAMCFG functional description 187
6.3.1 Internal SRAMs features 187
6.3.2 Parity error detection (SRAM2) 188
6.3.3 Write protection (SRAM2) 188
6.3.4 Software erase 188
6.4 RAMCFG in low-power modes 189
6.5 RAMCFG interrupts 189
6.6 RAMCFG registers 190
6.6.1 RAMCFG memory 1 control register (RAMCFG_M1CR) 190
6.6.2 RAMCFG memory 1 interrupt status register (RAMCFG_M1ISR) . . . 190
6.6.3 RAMCFG memory 2 control register (RAMCFG_M2CR) 191
6.6.4 RAMCFG memory 2 interrupt enable register (RAMCFG_M2IER) . . . 191
6.6.5 RAMCFG memory 2 interrupt status register (RAMCFG_M2ISR) . . . 192
6.6.6 RAMCFG memory 2 parity error address register (RAMCFG_M2PEAR) 192
6.6.7 RAMCFG memory 2 interrupt clear register (RAMCFG_M2ICR) 193

6.6.8 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1) . . . 193
6.6.9 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2) . . . 194
6.6.10 RAMCFG memory 2 parity key register (RAMCFG_M2PARKEYR) . . 194
6.6.11 RAMCFG memory x erase key register (RAMCFG_MxERKEYR) . . . 194
6.6.12 RAMCFG register map . . . 195

7 Embedded flash memory (FLASH) . . . 197

7.1 FLASH introduction . . . 197
7.2 FLASH main features . . . 197
7.3 FLASH functional description . . . 198
7.3.1 Flash memory organization . . . 198
7.3.2 Error code correction (ECC) . . . 199
7.3.3 Read access latency . . . 200
7.3.4 Bank power-down mode . . . 201
7.3.5 Flash memory program and erase operations . . . 202
7.3.6 Flash main memory erase sequences . . . 203
7.3.7 Flash memory programming sequences . . . 204
7.3.8 Flash memory errors flags . . . 206
7.3.9 Read-while-write (RWW) . . . 209
7.3.10 Power-down during flash programming or erase operation . . . 209
7.3.11 Reset during flash programming or erase operation . . . 209
7.4 FLASH option bytes . . . 210
7.4.1 Option-byte description . . . 210
7.4.2 Option-byte programming . . . 211
7.5 FLASH TrustZone security and privilege protections . . . 213
7.5.1 TrustZone security protection . . . 213
7.5.2 Watermark-based secure flash memory area protection . . . 214
7.5.3 Secure hide protection (HDP) . . . 215
7.5.4 Secure hide protection extension (HDP extension) . . . 216
7.5.5 Block-based secure flash memory area protection . . . 219
7.5.6 Flash security attribute state . . . 219
7.5.7 Block-based privileged flash memory area protection . . . 220
7.5.8 Flash memory register privileged and unprivileged modes . . . 220
7.5.9 Flash memory bank attributes in case of bank swap . . . 220

7.6 FLASH memory protection 222
7.6.1 Write protection (WRP) 222
7.6.2 Readout protection (RDP) 223
7.7 System memory 232
7.7.1 RSS user functions 232
7.8 Summary of flash memory and flash memory registers access control . 234
7.9 FLASH interrupts 237
7.10 FLASH registers 238
7.10.1 FLASH access control register (FLASH_ACR) 238
7.10.2 FLASH nonsecure key register (FLASH_KEYR) 239
7.10.3 FLASH secure key register (FLASH_SKEYR) 240
7.10.4 FLASH option key register (FLASH_OPTKEYR) 240
7.10.5 FLASH bank 1 power-down key register (FLASH_PDKEY1R) 241
7.10.6 FLASH bank 2 power-down key register (FLASH_PDKEY2R) 241
7.10.7 FLASH nonsecure status register (FLASH_SR) 242
7.10.8 FLASH secure status register (FLASH_SSR) 243
7.10.9 FLASH nonsecure control register (FLASH_CR) 245
7.10.10 FLASH secure control register (FLASH_SCR) 247
7.10.11 FLASH ECC register (FLASH_ECCCORR) 248
7.10.12 FLASH ECC detection register (FLASH_ECCDETR) 249
7.10.13 FLASH operation status register (FLASH_OPSR) 250
7.10.14 FLASH option register (FLASH_OPTR) 251
7.10.15 FLASH nonsecure boot address 0 register (FLASH_BOOT0R) 253
7.10.16 FLASH nonsecure boot address 1 register (FLASH_BOOT1R) 254
7.10.17 FLASH secure boot address 0 register (FLASH_SBOOT0R) 255
7.10.18 FLASH secure watermark1 register 1 (FLASH_SECWM1R1) 256
7.10.19 FLASH secure watermark1 register 2 (FLASH_SECWM1R2) 257
7.10.20 FLASH WRP1 area A address register (FLASH_WRP1AR) 258
7.10.21 FLASH WRP1 area B address register (FLASH_WRP1BR) 259
7.10.22 FLASH secure watermark2 register 1 (FLASH_SECWM2R1) 260
7.10.23 FLASH secure watermark2 register 2 (FLASH_SECWM2R2) 261
7.10.24 FLASH WPR2 area A address register (FLASH_WRP2AR) 262
7.10.25 FLASH WPR2 area B address register (FLASH_WRP2BR) 263
7.10.26 FLASH secure block based bank 1 register x (FLASH_SECBB1Rx) . 264
7.10.27 FLASH secure block based bank 2 register x (FLASH_SECBB2Rx) . 264

7.10.28 FLASH secure HDP control register (FLASH_SECHDPCR) 265
7.10.29 FLASH privilege configuration register (FLASH_PRIVCFGR) 266
7.10.30 FLASH HDP extension register (FLASH_SECHDPEXTR) 266
7.10.31 FLASH privilege block based bank 1 register x (FLASH_PRIVBB1Rx) 267
7.10.32 FLASH privilege block based bank 2 register x (FLASH_PRIVBB2Rx) 268
7.10.33 FLASH OEM1 key register 1 (FLASH_OEM1KEYR1) 268
7.10.34 FLASH OEM1 key register 2 (FLASH_OEM1KEYR2) 269
7.10.35 FLASH OEM1 key register 3 (FLASH_OEM1KEYR3) 269
7.10.36 FLASH OEM1 key register 4 (FLASH_OEM1KEYR4) 270
7.10.37 FLASH OEM2 key register 1 (FLASH_OEM2KEYR1) 270
7.10.38 FLASH OEM2 key register 2 (FLASH_OEM2KEYR2) 271
7.10.39 FLASH OEM2 key register 3 (FLASH_OEM2KEYR3) 271
7.10.40 FLASH OEM2 key register 4 (FLASH_OEM2KEYR4) 272
7.10.41 FLASH OEM key status register (FLASH_OEMKEYSR) 272
7.10.42 FLASH register map 273

8 Instruction cache (ICACHE) 277

8.1 ICACHE introduction 277
8.2 ICACHE main features 277
8.3 ICACHE implementation 278
8.4 ICACHE functional description 278
8.4.1 ICACHE block diagram 279
8.4.2 ICACHE reset and clocks 279
8.4.3 ICACHE TAG memory 280
8.4.4 Direct-mapped ICACHE (1-way cache) 281
8.4.5 ICACHE enable 282
8.4.6 Cacheable and noncacheable traffic 282
8.4.7 Address remapping 283
8.4.8 Cacheable accesses 285
8.4.9 Dual-master cache 286
8.4.10 ICACHE security 286
8.4.11 ICACHE maintenance 286
8.4.12 ICACHE performance monitoring 287
8.4.13 ICACHE boot 287
8.5 ICACHE low-power modes 287

8.6 ICACHE error management and interrupts 288
8.7 ICACHE registers 288
8.7.1 ICACHE control register (ICACHE_CR) 288
8.7.2 ICACHE status register (ICACHE_SR) 289
8.7.3 ICACHE interrupt enable register (ICACHE_IER) 290
8.7.4 ICACHE flag clear register (ICACHE_FCR) 290
8.7.5 ICACHE hit monitor register (ICACHE_HMONR) 291
8.7.6 ICACHE miss monitor register (ICACHE_MMONR) 291
8.7.7 ICACHE region x configuration register (ICACHE_CRRx) 291
8.7.8 ICACHE register map 293

9 Power control (PWR) 294
9.1 PWR introduction 294
9.2 PWR main features 294
9.3 PWR functional description 294
9.3.1 PWR pins and internal signals 294
9.3.2 PWR power supplies and supply domains 296
9.3.3 PWR system supply voltage regulation 300
9.3.4 PWR power supply supervision 302
9.3.5 PWR power management 305
9.3.6 PWR security and privileged protection 328
9.4 PWR interrupts 330
9.5 PWR registers 331
9.5.1 PWR control register 1 (PWR_CR1) 331
9.5.2 PWR control register 2 (PWR_CR2) 333
9.5.3 PWR control register 3 (PWR_CR3) 334
9.5.4 PWR voltage scaling register (PWR_VOSR) 335
9.5.5 PWR supply voltage monitoring control register (PWR_SVMCR) 336
9.5.6 PWR wake-up control register 1 (PWR_WUCR1) 338
9.5.7 PWR wake-up control register 2 (PWR_WUCR2) 338
9.5.8 PWR wake-up control register 3 (PWR_WUCR3) 339
9.5.9 PWR backup domain control register (PWR_BDCR) 340
9.5.10 PWR disable backup domain register (PWR_DBPR) 340
9.5.11 PWR security configuration register (PWR_SECCFGR) 341
9.5.12 PWR privilege control register (PWR_PRIVCFGR) 342
9.5.13 PWR status register (PWR_SR) 342

9.5.14 PWR supply voltage monitoring status register (PWR_SVMSR) 343
9.5.15 PWR wake-up status register (PWR_WUSR) 344
9.5.16 PWR wake-up status clear register (PWR_WUSCR) 344
9.5.17 PWR apply pull configuration register (PWR_APCR) 345
9.5.18 PWR port A pull-up control register (PWR_PUCRA) 345
9.5.19 PWR port A pull-down control register (PWR_PDCRA) 346
9.5.20 PWR port B pull-down control register (PWR_PDCRB) 347
9.5.21 PWR port x pull-up control register (PWR_PUCRx) (x = B to E) 348
9.5.22 PWR port x pull-down control register (PWR_PDCRx) (x = C to E) . . 349
9.5.23 PWR port G pull-up control register (PWR_PUCRG) 349
9.5.24 PWR port G pull-down control register (PWR_PDCRG) 350
9.5.25 PWR port H pull-up control register (PWR_PUCRH) 351
9.5.26 PWR port H pull-down control register (PWR_PDCRH) 351
9.5.27 PWR I3C pull-up control register 1 (PWR_I3CPUCR1) 352
9.5.28 PWR I3C pull-up control register 2 (PWR_I3CPUCR2) 353
9.5.29 PWR register map 354

10 Reset and clock control (RCC) 357

10.1 RCC introduction 357
10.2 RCC functional description 357
10.2.1 RCC pins and internal signals 357
10.2.2 RCC reset functional description 357
10.2.3 RCC clock functional description 359
10.2.4 RCC security and privilege functional description 374
10.3 RCC in low-power modes 377
10.4 RCC interrupts 378
10.5 RCC registers 380
10.5.1 RCC clock control register (RCC_CR) 380
10.5.2 RCC internal clock source calibration register 1 (RCC_ICSCR1) 383
10.5.3 RCC internal clock source calibration register 2 (RCC_ICSCR2) 386
10.5.4 RCC internal clock source calibration register 3 (RCC_ICSCR3) 387
10.5.5 RCC clock recovery RC register (RCC_CRRCR) 387
10.5.6 RCC clock configuration register 1 (RCC_CFGR1) 388
10.5.7 RCC clock configuration register 2 (RCC_CFGR2) 390
10.5.8 RCC clock configuration register 3 (RCC_CFGR3) 391
10.5.9 RCC clock configuration register 4 (RCC_CFGR4) 392
10.5.10 RCC clock interrupt enable register (RCC_CIER) 393

10.5.11 RCC clock interrupt flag register (RCC_CIFR) 394
10.5.12 RCC clock interrupt clear register (RCC_CICR) 396
10.5.13 RCC AHB1 peripheral reset register 1 (RCC_AHB1RSTR1) 397
10.5.14 RCC AHB2 peripheral reset register 1 (RCC_AHB2RSTR1) 398
10.5.15 RCC AHB2 peripheral reset register 2 (RCC_AHB2RSTR2) 399
10.5.16 RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1) 400
10.5.17 RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2) 401
10.5.18 RCC APB2 peripheral reset register (RCC_APB2RSTR) 402
10.5.19 RCC APB3 peripheral reset register (RCC_APB3RSTR) 403
10.5.20 RCC AHB1 peripheral clock enable register 1 (RCC_AHB1ENR1) . . . 403
10.5.21 RCC AHB2 peripheral clock enable register 1 (RCC_AHB2ENR1) . . . 405
10.5.22 RCC AHB2 peripheral clock enable register 2 (RCC_AHB2ENR2) . . . 406
10.5.23 RCC AHB1 peripheral clock enable register 2 (RCC_AHB1ENR2) . . . 406
10.5.24 RCC APB1 peripheral clock enable register 1 (RCC_APB1ENR1) . . . 407
10.5.25 RCC APB1 peripheral clock enable register 2 (RCC_APB1ENR2) . . . 409
10.5.26 RCC APB2 peripheral clock enable register (RCC_APB2ENR) 409
10.5.27 RCC APB3 peripheral clock enable register (RCC_APB3ENR) 410
10.5.28 RCC AHB1 peripheral clock enable in Sleep mode register (RCC_AHB1SLPENR1) 411
10.5.29 RCC AHB2 peripheral clock enable in Sleep mode register 1 (RCC_AHB2SLPENR1) 412
10.5.30 RCC AHB2 peripheral clock enable in Sleep mode register 2 (RCC_AHB2SLPENR2) 414
10.5.31 RCC AHB1 peripheral clock enable in Sleep mode register 2 (RCC_AHB1SLPENR2) 415
10.5.32 RCC APB1 peripheral clock enable in Sleep mode register 1 (RCC_APB1SLPENR1) 415
10.5.33 RCC APB1 peripheral clock enable in Sleep mode register 2 (RCC_APB1SLPENR2) 417
10.5.34 RCC APB2 peripheral clock enable in Sleep mode register (RCC_APB2SLPENR) 418
10.5.35 RCC APB3 peripheral clock enable in Sleep mode register (RCC_APB3SLPENR) 419
10.5.36 RCC AHB1 peripheral clock enable in Stop mode register (RCC_AHB1STPENR1) 420
10.5.37 RCC AHB2 peripheral clock enable in Stop mode register 1 (RCC_AHB2STPENR1) 421
10.5.38 RCC APB1 peripheral clock enable in Stop mode register 1 (RCC_APB1STPENR1) 422
10.5.39 RCC APB1 peripheral clock enable in Stop mode register 2 (RCC_APB1STPENR2) 423

10.5.40 RCC APB2 peripheral clock enable in Stop mode register (RCC_APB2STPENR) . . . 424
10.5.41 RCC APB3 peripheral clock enable in Stop mode register (RCC_APB3STPENR) . . . 425
10.5.42 RCC peripheral independent clock configuration register 1 (RCC_CCIPR1) . . . 426
10.5.43 RCC peripheral independent clock configuration register 2 (RCC_CCIPR2) . . . 428
10.5.44 RCC peripheral independent clock configuration register 3 (RCC_CCIPR3) . . . 430
10.5.45 RCC backup domain control register (RCC_BDCR) . . . 431
10.5.46 RCC control/status register (RCC_CSR) . . . 433
10.5.47 RCC secure configuration register (RCC_SECCFGR) . . . 435
10.5.48 RCC privilege configuration register (RCC_PRIVCFGR) . . . 436
10.5.49 RCC register map . . . 437

11 Clock recovery system (CRS) . . . 443

11.1 CRS introduction . . . 443
11.2 CRS main features . . . 443
11.3 CRS implementation . . . 443
11.4 CRS functional description . . . 444
11.4.1 CRS block diagram . . . 444
11.4.2 CRS internal signals . . . 444
11.4.3 Synchronization input . . . 445
11.4.4 Frequency error measurement . . . 445
11.4.5 Frequency error evaluation and automatic trimming . . . 446
11.4.6 CRS initialization and configuration . . . 447
11.5 CRS in low-power modes . . . 448
11.6 CRS interrupts . . . 448
11.7 CRS registers . . . 448
11.7.1 CRS control register (CRS_CR) . . . 448
11.7.2 CRS configuration register (CRS_CFGR) . . . 449
11.7.3 CRS interrupt and status register (CRS_ISR) . . . 450
11.7.4 CRS interrupt flag clear register (CRS_ICR) . . . 452
11.7.5 CRS register map . . . 453

12 General-purpose I/Os (GPIO) . . . 454

12.1 Introduction . . . 454

12.2 GPIO main features 454
12.3 GPIO functional description 454
12.3.1 General-purpose I/O (GPIO) 456
12.3.2 I/O pin alternate function multiplexer and mapping 457
12.3.3 I/O port control registers 457
12.3.4 I/O port state in low-power modes 458
12.3.5 I/O port data registers 458
12.3.6 I/O data bitwise handling 458
12.3.7 GPIO locking mechanism 458
12.3.8 I/O alternate function input/output 459
12.3.9 Input configuration 459
12.3.10 Output configuration 460
12.3.11 Alternate function configuration 460
12.3.12 Analog configuration 461
12.3.13 Using HSE or LSE oscillator pins as GPIOs 461
12.3.14 Using the GPIO pins in the RTC supply domain 462
12.3.15 Using BOOT0 pin as GPIO 462
12.3.16 TrustZone security 462
12.3.17 Privileged and unprivileged modes 463
12.3.18 High-speed low-voltage mode (HSLV) 463
12.3.19 I/O compensation cell 464
12.4 GPIO in low-power modes 464
12.5 GPIO interrupts 464
12.6 GPIO registers 465
12.6.1 GPIO port mode register (GPIOx_MODER) (x = A:E, G, H) 465
12.6.2 GPIO port output type register (GPIOx_OTYPER) (x = A:E, G, H) . . . 466
12.6.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A:E, G, H) 466
12.6.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A:E, G, H) 467
12.6.5 GPIO port input data register (GPIOx_IDR) (x = A:E, G, H) 468
12.6.6 GPIO port output data register (GPIOx_ODR) (x = A:E, G, H) 468
12.6.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A:E, G, H) 469
12.6.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A:E, G, H) . 470
12.6.9 GPIO alternate function low register (GPIOx_AFRL) (x = A:E, G, H) . 471
12.6.10 GPIO alternate function high register (GPIOx_AFRH) (x = A:E, G, H) 471
12.6.11 GPIO port bit reset register (GPIOx_BRR) (x = A:E, G, H) 472
12.6.12 GPIO high-speed low-voltage register (GPIOx_HSLVR) (x = A:E, G, H) 473

12.6.13 GPIO secure configuration register (GPIOx_SECCFGR) (x = A:E, G, H) . . . 474
12.6.14 GPIO register map . . . 474

13 System configuration controller (SYSCFG) . . . 476
13.1 SYSCFG main features . . . 476
13.2 SYSCFG functional description . . . 476
13.2.1 I/O compensation cell management . . . 476
13.2.2 SYSCFG TrustZone security and privilege . . . 477
13.2.3 GPIO analog switches supply selection . . . 478
13.3 SYSCFG registers . . . 479
13.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR) . . . 479
13.3.2 SYSCFG configuration register 1 (SYSCFG_CFGR1) . . . 480
13.3.3 SYSCFG FPU interrupt mask register (SYSCFG_FPUIMR) . . . 481
13.3.4 SYSCFG CPU nonsecure lock register (SYSCFG_CNSLCKR) . . . 482
13.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLCKR) . . . 483
13.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2) . . . 484
13.3.7 SYSCFG compensation cell control/status register (SYSCFG_CCCSR) . . . 485
13.3.8 SYSCFG compensation cell value register (SYSCFG_CCVR) . . . 486
13.3.9 SYSCFG compensation cell code register (SYSCFG_CCCR) . . . 487
13.3.10 SYSCFG RSS command register (SYSCFG_RSSCMDR) . . . 488
13.3.11 SYSCFG register map . . . 488

14 Peripherals interconnect matrix . . . 490
14.1 Interconnect matrix introduction . . . 490
14.2 Connection summary . . . 490
14.3 Interconnection details . . . 492
14.3.1 Master to slave interconnection for timers . . . 492
14.3.2 Triggers to ADCs . . . 492
14.3.3 ADC analog watchdogs as triggers to timers . . . 493
14.3.4 Triggers to DAC . . . 494
14.3.5 Triggers to ADF1 . . . 494
14.3.6 Data input to ADF1 . . . 494
14.3.7 Clock sources to timers . . . 495
14.3.8 Triggers to low-power timers . . . 496
14.3.9 Blanking sources to comparators . . . 496

14.3.10 RTC wake-up as inputs to timers . . . 497
14.3.11 USB SOF as trigger to timers . . . 497
14.3.12 Comparators as inputs, trigger or break signals to timers . . . 497
14.3.13 System errors as break signals to timers . . . 498
14.3.14 Timers generating IRTIM signal . . . 499
14.3.15 Triggers for communication peripherals . . . 499
14.3.16 Triggers to GPDMA . . . 500
14.3.17 Internal analog signals to analog peripherals . . . 501
14.3.18 Clock source for the DAC sample and hold mode . . . 501
14.3.19 Internal tamper sources . . . 502
14.3.20 Output from tamper to RTC . . . 502
14.3.21 Encryption keys to AES/SAES . . . 502
14.3.22 I3C IBI acknowledge to timers from I3C1/2 to TIM15/16/17 and LPTIM1/2/3 . . . 503

15 General purpose direct memory access controller (GPDMA) . . . 504

15.1 GPDMA introduction . . . 504
15.2 GPDMA main features . . . 504
15.3 GPDMA implementation . . . 505
15.3.1 GPDMA channels . . . 505
15.3.2 GPDMA in low-power modes . . . 506
15.3.3 GPDMA requests . . . 506
15.3.4 GPDMA block requests . . . 509
15.3.5 GPDMA channels with peripheral early termination . . . 510
15.3.6 GPDMA triggers . . . 510
15.4 GPDMA functional description . . . 512
15.4.1 GPDMA block diagram . . . 512
15.4.2 GPDMA channel state and direct programming without any linked-list 512
15.4.3 GPDMA channel suspend and resume . . . 513
15.4.4 GPDMA channel abort and restart . . . 514
15.4.5 GPDMA linked-list data structure . . . 515
15.4.6 Linked-list item transfer execution . . . 518
15.4.7 GPDMA channel state and linked-list programming in run-to-completion mode . . . 519
15.4.8 GPDMA channel state and linked-list programming in link step mode 522
15.4.9 GPDMA channel state and linked-list programming . . . 529
15.4.10 GPDMA FIFO-based transfers . . . 531

15.4.11 GPDMA transfer request and arbitration 538
15.4.12 GPDMA triggered transfer 542
15.4.13 GPDMA circular buffering with linked-list programming 543
15.4.14 GPDMA transfer in peripheral flow-control mode 545
15.4.15 GPDMA secure/nonsecure channel 546
15.4.16 GPDMA privileged/unprivileged channel 547
15.4.17 GPDMA error management 547
15.5 GPDMA in debug mode 549
15.6 GPDMA in low-power modes 549
15.7 GPDMA interrupts 550
15.8 GPDMA registers 551
15.8.1 GPDMA secure configuration register (GPDMA_SECCFGR) 551
15.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR) 552
15.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR) 552
15.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR) 553
15.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR) . . 554
15.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR) 554
15.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR) 555
15.8.8 GPDMA channel x status register (GPDMA_CxSR) 556
15.8.9 GPDMA channel x control register (GPDMA_CxCR) 557
15.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1) 559
15.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2) 563
15.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1) 567
15.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1) 568
15.8.14 GPDMA channel x source address register (GPDMA_CxSAR) 571
15.8.15 GPDMA channel x destination address register (GPDMA_CxDAR) . . 572
15.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3) 573
15.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2) 574
15.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR) 575
15.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR) 577
15.8.20 GPDMA register map 578

16 Nested vectored interrupt controller (NVIC) 580
16.1 NVIC main features 580

16.2 SysTick calibration value register 580
16.3 Interrupt and exception vectors 581

17 Extended interrupts and event controller (EXTI) 587
17.1 EXTI introduction 587
17.2 EXTI main features 587
17.3 EXTI functional description 587
17.3.1 EXTI block diagram 587
17.3.2 Event features control 589
17.3.3 EXTI configurable event input wake-up 590
17.3.4 EXTI mux selection 590
17.3.5 EXTI functional behavior 591
17.3.6 EXTI event protection 592
17.4 EXTI registers 593
17.4.1 EXTI rising trigger selection register (EXTI_RTSR1) 593
17.4.2 EXTI falling trigger selection register (EXTI_FTSR1) 594
17.4.3 EXTI software interrupt event register (EXTI_SWIER1) 594
17.4.4 EXTI rising edge pending register (EXTI_RPR1) 595
17.4.5 EXTI falling edge pending register (EXTI_FPR1) 596
17.4.6 EXTI security configuration register (EXTI_SECCFGR1) 596
17.4.7 EXTI privilege configuration register (EXTI_PRIVCFGR1) 597
17.4.8 EXTI external interrupt selection register (EXTI_EXTICRx) 597
17.4.9 EXTI lock register (EXTI_LOCKR) 600
17.4.10 EXTI CPU wake-up with interrupt mask register (EXTI_IMR1) 600
17.4.11 EXTI CPU wake-up with event mask register (EXTI_EMR1) 601
17.4.12 EXTI register map 601

18 Cyclic redundancy check calculation unit (CRC) 603
18.1 Introduction 603
18.2 CRC main features 603
18.3 CRC functional description 604
18.3.1 CRC block diagram 604
18.3.2 CRC internal signals 604
18.3.3 CRC operation 604
18.4 CRC registers 606
18.4.1 CRC data register (CRC_DR) 606

18.4.2 CRC independent data register (CRC_IDR) 606
18.4.3 CRC control register (CRC_CR) 607
18.4.4 CRC initial value (CRC_INIT) 608
18.4.5 CRC polynomial (CRC_POL) 608
18.4.6 CRC register map 609

19 Extended-SPI interface (OCTOSPI) 610

19.1 OCTOSPI introduction 610
19.2 OCTOSPI main features 610
19.3 OCTOSPI implementation 611
19.4 OCTOSPI functional description 612
19.4.1 OCTOSPI block diagram 612
19.4.2 OCTOSPI pins and internal signals 613
19.4.3 OCTOSPI interface to memory modes 614
19.4.4 OCTOSPI regular-command protocol 614
19.4.5 OCTOSPI regular-command protocol signal interface 618
19.4.6 HyperBus protocol 621
19.4.7 Specific features 625
19.4.8 OCTOSPI operating mode introduction 626
19.4.9 OCTOSPI indirect mode 626
19.4.10 OCTOSPI automatic status-polling mode 628
19.4.11 OCTOSPI memory-mapped mode 629
19.4.12 OCTOSPI configuration introduction 630
19.4.13 OCTOSPI system configuration 630
19.4.14 OCTOSPI device configuration 630
19.4.15 OCTOSPI regular-command mode configuration 633
19.4.16 OCTOSPI HyperBus protocol configuration 635
19.4.17 OCTOSPI error management 636
19.4.18 OCTOSPI BUSY and ABORT 637
19.4.19 OCTOSPI reconfiguration or deactivation 637
19.4.20 NCS behavior 637
19.5 Address alignment and data number 639
19.6 OCTOSPI interrupts 640
19.7 OCTOSPI registers 641
19.7.1 OCTOSPI control register (OCTOSPI_CR) 641
19.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1) 643

19.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2) 645
19.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3) 646
19.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4) 646
19.7.6 OCTOSPI status register (OCTOSPI_SR) 647
19.7.7 OCTOSPI flag clear register (OCTOSPI_FCR) 648
19.7.8 OCTOSPI data length register (OCTOSPI_DLR) 648
19.7.9 OCTOSPI address register (OCTOSPI_AR) 649
19.7.10 OCTOSPI data register (OCTOSPI_DR) 649
19.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR) 650
19.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR) 651
19.7.13 OCTOSPI polling interval register (OCTOSPI_PIR) 651
19.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR) . . 651
19.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR) 654
19.7.16 OCTOSPI instruction register (OCTOSPI_IR) 654
19.7.17 OCTOSPI alternate bytes register (OCTOSPI_ABR) 655
19.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR) 655
19.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR) 656
19.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR) . . 658
19.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR) 658
19.7.22 OCTOSPI wrap alternate bytes register (OCTOSPI_WPABR) 659
19.7.23 OCTOSPI write communication configuration register (OCTOSPI_WCCR) 659
19.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR) 661
19.7.25 OCTOSPI write instruction register (OCTOSPI_WIR) 662
19.7.26 OCTOSPI write alternate bytes register (OCTOSPI_WABR) 662
19.7.27 OCTOSPI HyperBus latency configuration register (OCTOSPI_HLCR) 663
19.7.28 OCTOSPI register map 663

20 Secure digital input/output MultiMediaCard interface (SDMMC) . . . 667

20.1 SDMMC main features 667
20.2 SDMMC implementation 667
20.3 SDMMC bus topology 668
20.4 SDMMC operation modes 670
20.5 SDMMC functional description 671
20.5.1 SDMMC block diagram 671

20.5.2 SDMMC pins and internal signals . . . 671
20.5.3 General description . . . 672
20.5.4 SDMMC adapter . . . 674
20.5.5 SDMMC AHB slave interface . . . 696
20.5.6 SDMMC AHB master interface . . . 697
20.5.7 AHB and SDMMC_CK clock relation . . . 700
20.6 Card functional description . . . 700
20.6.1 SD I/O mode . . . 700
20.6.2 CMD12 send timing . . . 708
20.6.3 Sleep (CMD5) . . . 712
20.6.4 Interrupt mode (Wait-IRQ) . . . 713
20.6.5 Boot operation . . . 714
20.6.6 Response R1b handling . . . 717
20.6.7 Reset and card cycle power . . . 718
20.7 Hardware flow control . . . 719
20.8 Ultra-high-speed phase I (UHS-I) voltage switch . . . 719
20.9 SDMMC interrupts . . . 722
20.10 SDMMC registers . . . 724
20.10.1 SDMMC power control register (SDMMC_POWER) . . . 724
20.10.2 SDMMC clock control register (SDMMC_CLKCR) . . . 725
20.10.3 SDMMC argument register (SDMMC_ARGR) . . . 727
20.10.4 SDMMC command register (SDMMC_CMDR) . . . 727
20.10.5 SDMMC command response register (SDMMC_RESPCMDR) . . . 729
20.10.6 SDMMC response x register (SDMMC_RESPxR) . . . 730
20.10.7 SDMMC data timer register (SDMMC_DTIMER) . . . 730
20.10.8 SDMMC data length register (SDMMC_DLENR) . . . 731
20.10.9 SDMMC data control register (SDMMC_DCTRL) . . . 732
20.10.10 SDMMC data counter register (SDMMC_DCNTR) . . . 733
20.10.11 SDMMC status register (SDMMC_STAR) . . . 734
20.10.12 SDMMC interrupt clear register (SDMMC_ICR) . . . 737
20.10.13 SDMMC mask register (SDMMC_MASKR) . . . 739
20.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER) . . . 742
20.10.15 SDMMC DMA control register (SDMMC_IDMACTRLR) . . . 742
20.10.16 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER) . . . 743
20.10.17 SDMMC IDMA buffer base address register (SDMMC_IDMABASER) . . . 744
20.10.18 SDMMC IDMA linked list address register (SDMMC_IDMALAR) . . . 744

20.10.19 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR) . . . 745
20.10.20 SDMMC data FIFO registers x (SDMMC_FIFORx) . . . 746
20.10.21 SDMMC register map . . . 746

21 Delay block (DLYB) . . . 749
21.1 Introduction . . . 749
21.2 DLYB main features . . . 749
21.3 DLYB implementation . . . 749
21.4 DLYB functional description . . . 749
21.4.1 DLYB diagram . . . 749
21.4.2 DLYB pins and internal signals . . . 750
21.4.3 General description . . . 750
21.4.4 Delay line length configuration procedure . . . 751
21.4.5 Output clock phase configuration procedure . . . 752
21.5 DLYB registers . . . 752
21.5.1 DLYB control register (DLYB_CR) . . . 752
21.5.2 DLYB configuration register (DLYB_CFGR) . . . 753
21.5.3 DLYB register map . . . 754

22 Analog-to-digital converters (ADC) . . . 755
22.1 Introduction . . . 755
22.2 ADC main features . . . 755
22.3 ADC implementation . . . 757
22.4 ADC functional description . . . 758
22.4.1 ADC block diagram . . . 758
22.4.2 ADC pins and internal signals . . . 759
22.4.3 ADC clocks . . . 762
22.4.4 ADC connectivity . . . 763
22.4.5 Slave AHB interface . . . 765
22.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) . . . 765
22.4.7 Calibration (ADCAL) . . . 765
22.4.8 ADC on-off control (ADEN, ADDIS, ADRDY) . . . 767
22.4.9 Constraints when writing the ADC control bits . . . 768
22.4.10 Channel selection (ADC_SQRy, ADC_JSQR) . . . 769
22.4.11 Channel preselection register (ADC_PCSEL) . . . 770

22.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2) 770
22.4.13 Single conversion mode 772
22.4.14 Continuous conversion mode (CONT = 1) 773
22.4.15 Starting conversions (ADSTART, JADSTART) 773
22.4.16 Timing 774
22.4.17 Stopping an ongoing conversion (ADSTP, JADSTP) 775
22.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) 777
22.4.19 Injected channel management 778
22.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) 779
22.4.21 Queue of context for injected conversions 781
22.4.22 Programmable resolution (RES) - fast conversion mode 789
22.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP) 790
22.4.24 End of conversion sequence (EOS, JEOS) 790
22.4.25 Timing diagram examples (single/continuous modes, hardware/software triggers) 791
22.4.26 Data management 793
22.4.27 Managing conversions using the ADF 801
22.4.28 Dynamic low-power features 802
22.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT) 806
22.4.30 Oversampler 811
22.4.31 Dual ADC modes 817
22.4.32 Temperature sensor 832
22.4.33 VBAT supply monitoring 834
22.4.34 Monitoring the internal voltage reference 835
22.4.35 Monitoring the DAC output voltage 837
22.4.36 Monitoring the supply voltage 837
22.5 ADC in low-power modes 838
22.6 ADC interrupts 838
22.7 ADC registers (for each ADC) 839
22.7.1 ADC interrupt and status register (ADC_ISR) 839
22.7.2 ADC interrupt enable register (ADC_IER) 842
22.7.3 ADC control register (ADC_CR) 844
22.7.4 ADC configuration register (ADC_CFGR1) 847
22.7.5 ADC configuration register 2 (ADC_CFGR2) 851

22.7.6 ADC sample time register 1 (ADC_SMPR1) 853
22.7.7 ADC sample time register 2 (ADC_SMPR2) 854
22.7.8 ADC channel preselection register (ADC_PCSEL) 855
22.7.9 ADC regular sequence register 1 (ADC_SQR1) 855
22.7.10 ADC regular sequence register 2 (ADC_SQR2) 856
22.7.11 ADC regular sequence register 3 (ADC_SQR3) 857
22.7.12 ADC regular sequence register 4 (ADC_SQR4) 858
22.7.13 ADC regular data register (ADC_DR) 859
22.7.14 ADC injected sequence register (ADC_JSQR) 859
22.7.15 ADC offset y configuration register (ADC_OFCFGRy) 861
22.7.16 ADC offset y register (ADC_OFRy) 862
22.7.17 ADC gain compensation register (ADC_GCOMP) 862
22.7.18 ADC injected channel y data register (ADC_JDRy) 863
22.7.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR) 864
22.7.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR) 864
22.7.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR) . 865
22.7.22 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR) 865
22.7.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR) . 866
22.7.24 ADC analog watchdog 2 higher threshold register (ADC_AWD2HTR) 866
22.7.25 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR) . 867
22.7.26 ADC analog watchdog 3 higher threshold register (ADC_AWD3HTR) 867
22.7.27 ADC calibration factors (ADC_CALFACT) 867
22.7.28 ADC option register (ADC_OR) 869
22.8 ADC common registers 869
22.8.1 ADC common status register (ADCC_CSR) 869
22.8.2 ADC common control register (ADCC_CCR) 871
22.8.3 ADC common regular data register for dual mode (ADCC_CDR) 873
22.8.4 ADC common regular data register for dual mode (ADCC_CDR2) 873
22.9 ADC register map 874

23 Digital-to-analog converter (DAC) 878

23.1 Introduction 878

23.2 DAC main features . . . 878
23.3 DAC implementation . . . 879
23.4 DAC functional description . . . 880
23.4.1 DAC block diagram . . . 880
23.4.2 DAC pins and internal signals . . . 881
23.4.3 DAC clocks . . . 882
23.4.4 DAC channel enable . . . 882
23.4.5 DAC data format . . . 883
23.4.6 DAC conversion . . . 884
23.4.7 DAC output voltage . . . 885
23.4.8 DAC trigger selection . . . 886
23.4.9 DMA requests . . . 886
23.4.10 Noise generation . . . 887
23.4.11 Triangle-wave generation . . . 888
23.4.12 DAC channel modes . . . 889
23.4.13 DAC channel buffer calibration . . . 892
23.4.14 DAC channel conversion modes . . . 893
23.4.15 Dual DAC channel conversion modes (if dual channels are available) . . . 894
23.4.16 DAC autonomous mode . . . 898
23.5 DAC in low-power modes . . . 899
23.6 DAC interrupts . . . 900
23.7 DAC registers . . . 900
23.7.1 DAC control register (DAC_CR) . . . 900
23.7.2 DAC software trigger register (DAC_SWTRGR) . . . 903
23.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1) . . . 904
23.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1) . . . 905
23.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1) . . . 905
23.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2) . . . 906
23.7.7 DAC channel2 12-bit left aligned data holding register (DAC_DHR12L2) . . . 906
23.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2) . . . 907
23.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD) . . . 907

23.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD) . . . 908
23.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD) . . . 908
23.7.12 DAC channel1 data output register (DAC_DOR1) . . . 909
23.7.13 DAC channel2 data output register (DAC_DOR2) . . . 909
23.7.14 DAC status register (DAC_SR) . . . 910
23.7.15 DAC calibration control register (DAC_CCR) . . . 911
23.7.16 DAC mode control register (DAC_MCR) . . . 912
23.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1) . . . 913
23.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2) . . . 914
23.7.19 DAC sample and hold time register (DAC_SHHR) . . . 914
23.7.20 DAC sample and hold refresh time register (DAC_SHRR) . . . 915
23.7.21 DAC autonomous mode control register (DAC_AUTOCR) . . . 916
23.7.22 DAC register map . . . 916

24 Voltage reference buffer (VREFBUF) . . . 919

24.1 Introduction . . . 919
24.2 VREFBUF implementation . . . 919
24.3 VREFBUF functional description . . . 919
24.4 VREFBUF trimming . . . 920
24.5 VREFBUF registers . . . 921
24.5.1 VREFBUF control and status register (VREFBUF_CSR) . . . 921
24.5.2 VREFBUF calibration control register (VREFBUF_CCR) . . . 922
24.5.3 VREFBUF register map . . . 922

25 Comparator (COMP) . . . 923

25.1 Introduction . . . 923
25.2 COMP main features . . . 923
25.3 COMP functional description . . . 924
25.3.1 COMP block diagram . . . 924
25.3.2 COMP pins and internal signals . . . 924
25.3.3 Comparator LOCK mechanism . . . 926
25.3.4 Window comparator . . . 926
25.3.5 Hysteresis . . . 927

25.3.6 Comparator output-blanking function . . . 927
25.3.7 COMP power and speed modes . . . 928
25.3.8 Scaler function . . . 928
25.4 COMP in low-power modes . . . 929
25.5 COMP interrupts . . . 929
25.6 COMP registers . . . 930
25.6.1 COMP1 control and status register (COMP1_CSR) . . . 930
25.6.2 COMP2 control and status register (COMP2_CSR) . . . 932
25.6.3 COMP register map . . . 933

26 Operational amplifier (OPAMP) . . . 934
26.1 OPAMP introduction . . . 934
26.2 OPAMP main features . . . 934
26.3 OPAMP functional description . . . 934
26.3.1 OPAMP reset and clocks . . . 934
26.3.2 Initial configuration . . . 935
26.3.3 Signal routing . . . 935
26.3.4 OPAMP modes . . . 936
26.3.5 Calibration . . . 939
26.4 OPAMP low-power modes . . . 941
26.5 OPAMP registers . . . 941
26.5.1 OPAMP1 control/status register (OPAMP1_CSR) . . . 941
26.5.2 OPAMP1 offset trimming register in normal mode (OPAMP1_OTR) . . 943
26.5.3 OPAMP1 offset trimming register in low-power mode (OPAMP1_LPOTR) . . . 943
26.5.4 OPAMP2 control/status register (OPAMP2_CRS) . . . 944
26.5.5 OPAMP2 offset trimming register in normal mode (OPAMP2_OTR) . . . 945
26.5.6 OPAMP2 offset trimming register in low-power mode (OPAMP2_LPOTR) . . . 945
26.5.7 OPAMP register map . . . 946

27 Audio digital filter (ADF) . . . 947
27.1 ADF introduction . . . 947
27.2 ADF main features . . . 947
27.3 ADF implementation . . . 948
27.4 ADF functional description . . . 949

27.4.1 ADF block diagram . . . 949
27.4.2 ADF pins and internal signals . . . 949
27.4.3 Serial input interface (SITF) . . . 950
27.4.4 ADC slave interface (ADCITF) . . . 955
27.4.5 Clock generator (CKGEN) . . . 956
27.4.6 Bitstream matrix (BSMX) . . . 958
27.4.7 Digital filter processing (DFLT) . . . 959
27.4.8 Digital filter acquisition modes . . . 968
27.4.9 Start-up sequence examples . . . 976
27.4.10 Sound activity detection (SAD) . . . 977
27.4.11 Data transfer to memory . . . 985
27.4.12 Autonomous mode . . . 988
27.4.13 Register protection . . . 988
27.5 ADF low-power modes . . . 989
27.6 ADF interrupts . . . 989
27.7 ADF application information . . . 991
27.7.1 ADF configuration examples for audio capture . . . 991
27.7.2 Programming examples . . . 992
27.7.3 Connection examples . . . 994
27.7.4 Global frequency response . . . 995
27.7.5 Total ADF gain . . . 996
27.7.6 How to compute SAD thresholds . . . 999
27.8 ADF registers . . . 1003
27.8.1 ADF global control register (ADF_GCR) . . . 1003
27.8.2 ADF clock generator control register (ADF_CKGCR) . . . 1004
27.8.3 ADF trigger input selection register (ADF_TRGISEL) . . . 1006
27.8.4 ADF serial interface control register 0 (ADF_SITF0CR) . . . 1007
27.8.5 ADF bitstream matrix control register 0 (ADF_BSMX0CR) . . . 1008
27.8.6 ADF digital filter control register 0 (ADF_DFLT0CR) . . . 1008
27.8.7 ADF digital filer configuration register 0 (ADF_DFLT0CICR) . . . 1010
27.8.8 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR) . . . 1012
27.8.9 ADF delay control register 0 (ADF_DLY0CR) . . . 1013
27.8.10 ADF DFLT0 interrupt enable register (ADF_DFLT0IER) . . . 1013
27.8.11 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR) . . . 1014
27.8.12 ADF SAD control register (ADF_SADCR) . . . 1015
27.8.13 ADF SAD configuration register (ADF_SADCFGR) . . . 1017
27.8.14 ADF SAD sound level register (ADF_SADSDLVR) . . . 1019

27.8.15 ADF SAD ambient noise level register (ADF_SADANLVR) 1019
27.8.16 ADF digital filter data register 0 (ADF_DFLT0DR) 1020
27.8.17 ADF register map 1020

28 Touch sensing controller (TSC) 1023
28.1 Introduction 1023
28.2 TSC main features 1023
28.3 TSC functional description 1024
28.3.1 TSC block diagram 1024
28.3.2 Surface charge transfer acquisition overview 1024
28.3.3 Reset and clocks 1027
28.3.4 Charge transfer acquisition sequence 1027
28.3.5 Spread spectrum feature 1028
28.3.6 Max count error 1029
28.3.7 Sampling capacitor I/O and channel I/O mode selection 1029
28.3.8 Acquisition mode 1030
28.3.9 I/O hysteresis and analog switch control 1030
28.4 TSC low-power modes 1031
28.5 TSC interrupts 1031
28.6 TSC registers 1031
28.6.1 TSC control register (TSC_CR) 1031
28.6.2 TSC interrupt enable register (TSC_IER) 1034
28.6.3 TSC interrupt clear register (TSC_ICR) 1035
28.6.4 TSC interrupt status register (TSC_ISR) 1035
28.6.5 TSC I/O hysteresis control register (TSC_IOHCR) 1036
28.6.6 TSC I/O analog switch control register (TSC_IOASCR) 1036
28.6.7 TSC I/O sampling control register (TSC_IOSCR) 1037
28.6.8 TSC I/O channel control register (TSC_IOCCR) 1037
28.6.9 TSC I/O group control status register (TSC_IOGCSR) 1038
28.6.10 TSC I/O group x counter register (TSC_IOGxCR) 1038
28.6.11 TSC register map 1039

29 Coupling and chaining bridge (CCB) 1041
29.1 CCB introduction 1041
29.2 CCB main features 1041

29.3 CCB implementation 1042
29.4 CCB functional description 1042
29.4.1 CCB block diagram 1042
29.4.2 CCB internal signals 1043
29.4.3 CCB reset and clocks 1043
29.4.4 CCB coupling and chaining 1043
29.5 CCB coupling and chaining operations 1046
29.5.1 Preliminary steps before any protected operation 1048
29.5.2 ECDSA signature 1048
29.5.3 ECC scalar multiplication 1054
29.5.4 RSA modular exponentiation 1057
29.5.5 CCB error 1059
29.6 CCB interrupts 1059
29.7 CCB registers 1060
29.7.1 CCB control register (CCB_CR) 1060
29.7.2 CCB status register (CCB_SR) 1061
29.7.3 CCB reference tag register (CCB_REFTAGRx) 1063
29.7.4 CCB register map 1064

30 True random number generator (RNG) 1065
30.1 Introduction 1065
30.2 RNG main features 1065
30.3 RNG functional description 1066
30.3.1 RNG block diagram 1066
30.3.2 RNG internal signals 1066
30.3.3 Random number generation 1067
30.3.4 RNG initialization 1070
30.3.5 RNG operation 1071
30.3.6 RNG clocking 1072
30.3.7 Error management 1072
30.3.8 RNG low-power use 1073
30.4 RNG interrupts 1074
30.5 RNG processing time 1074
30.6 RNG entropy source validation 1075
30.6.1 Introduction 1075
30.6.2 Validation conditions 1075

30.7 RNG registers . . . 1076
30.7.1 RNG control register (RNG_CR) . . . 1076
30.7.2 RNG status register (RNG_SR) . . . 1078
30.7.3 RNG data register (RNG_DR) . . . 1079
30.7.4 RNG noise source control register (RNG_NSCR) . . . 1080
30.7.5 RNG health test control register x (RNG_HTCRx) . . . 1080
30.7.6 RNG register map . . . 1081

31 AES hardware accelerator (AES) . . . 1082
31.1 Introduction . . . 1082
31.2 AES main features . . . 1082
31.3 AES implementation . . . 1083
31.4 AES functional description . . . 1083
31.4.1 AES block diagram . . . 1083
31.4.2 AES internal signals . . . 1084
31.4.3 AES reset and clocks . . . 1084
31.4.4 AES symmetric cipher implementation . . . 1084
31.4.5 AES encryption or decryption typical usage . . . 1085
31.4.6 AES authenticated encryption, decryption, and cipher-based message authentication . . . 1087
31.4.7 AES ciphertext stealing and data padding . . . 1087
31.4.8 AES suspend and resume operations . . . 1088
31.4.9 AES basic chaining modes (ECB, CBC) . . . 1089
31.4.10 AES counter (CTR) mode . . . 1092
31.4.11 AES Galois/counter mode (GCM) . . . 1095
31.4.12 AES Galois message authentication code (GMAC) . . . 1099
31.4.13 AES counter with CBC-MAC (CCM) . . . 1100
31.4.14 AES key sharing with secure AES co-processor . . . 1105
31.4.15 AES data registers and data swapping . . . 1106
31.4.16 AES key registers . . . 1108
31.4.17 AES initialization vector registers . . . 1108
31.4.18 AES error management . . . 1109
31.5 AES interrupts . . . 1110
31.6 AES DMA requests . . . 1110
31.7 AES processing latency . . . 1111
31.8 AES registers . . . 1113

31.8.1 AES control register (AES_CR) 1113
31.8.2 AES status register (AES_SR) 1115
31.8.3 AES data input register (AES_DINR) 1116
31.8.4 AES data output register (AES_DOUTR) 1117
31.8.5 AES key register 0 (AES_KEYR0) 1117
31.8.6 AES key register 1 (AES_KEYR1) 1118
31.8.7 AES key register 2 (AES_KEYR2) 1118
31.8.8 AES key register 3 (AES_KEYR3) 1118
31.8.9 AES initialization vector register 0 (AES_IVR0) 1119
31.8.10 AES initialization vector register 1 (AES_IVR1) 1119
31.8.11 AES initialization vector register 2 (AES_IVR2) 1119
31.8.12 AES initialization vector register 3 (AES_IVR3) 1120
31.8.13 AES key register 4 (AES_KEYR4) 1120
31.8.14 AES key register 5 (AES_KEYR5) 1120
31.8.15 AES key register 6 (AES_KEYR6) 1121
31.8.16 AES key register 7 (AES_KEYR7) 1121
31.8.17 AES suspend registers (AES_SUSPRx) 1121
31.8.18 AES interrupt enable register (AES_IER) 1122
31.8.19 AES interrupt status register (AES_ISR) 1123
31.8.20 AES interrupt clear register (AES_ICR) 1124
31.8.21 AES register map 1124

32 Secure AES coprocessor (SAES) 1127

32.1 Introduction 1127
32.2 SAES main features 1127
32.3 SAES implementation 1128
32.4 SAES functional description 1128
32.4.1 SAES block diagram 1128
32.4.2 SAES internal signals 1129
32.4.3 SAES reset and clocks 1130
32.4.4 SAES symmetric cipher implementation 1130
32.4.5 SAES encryption or decryption typical usage 1131
32.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication 1133
32.4.7 SAES ciphertext stealing and data padding 1134
32.4.8 SAES suspend and resume operations 1134
32.4.9 SAES basic chaining modes (ECB, CBC) 1135

32.4.10 SAES counter (CTR) mode 1139
32.4.11 SAES Galois/counter mode (GCM) 1141
32.4.12 SAES Galois message authentication code (GMAC) 1145
32.4.13 SAES counter with CBC-MAC (CCM) 1147
32.4.14 SAES operation with wrapped keys 1152
32.4.15 SAES operation with shared keys 1156
32.4.16 SAES data registers and data swapping 1157
32.4.17 SAES key registers 1160
32.4.18 SAES initialization vector registers 1161
32.4.19 SAES error management 1162
32.5 SAES interrupts 1164
32.6 SAES DMA requests 1164
32.7 SAES processing latency 1165
32.8 SAES registers 1167
32.8.1 SAES control register (SAES_CR) 1167
32.8.2 SAES status register (SAES_SR) 1170
32.8.3 SAES data input register (SAES_DINR) 1171
32.8.4 SAES data output register (SAES_DOUTR) 1172
32.8.5 SAES key register 0 (SAES_KEYR0) 1172
32.8.6 SAES key register 1 (SAES_KEYR1) 1173
32.8.7 SAES key register 2 (SAES_KEYR2) 1173
32.8.8 SAES key register 3 (SAES_KEYR3) 1173
32.8.9 SAES initialization vector register 0 (SAES_IVR0) 1174
32.8.10 SAES initialization vector register 1 (SAES_IVR1) 1174
32.8.11 SAES initialization vector register 2 (SAES_IVR2) 1174
32.8.12 SAES initialization vector register 3 (SAES_IVR3) 1175
32.8.13 SAES key register 4 (SAES_KEYR4) 1175
32.8.14 SAES key register 5 (SAES_KEYR5) 1175
32.8.15 SAES key register 6 (SAES_KEYR6) 1176
32.8.16 SAES key register 7 (SAES_KEYR7) 1176
32.8.17 SAES suspend registers (SAES_SUSPRx) 1176
32.8.18 SAES interrupt enable register (SAES_IER) 1177
32.8.19 SAES interrupt status register (SAES_ISR) 1178
32.8.20 SAES interrupt clear register (SAES_ICR) 1179
32.8.21 SAES register map 1180

33 Hash processor (HASH) 1182

33.1 Introduction 1182
33.2 HASH main features 1182
33.3 HASH implementation 1183
33.4 HASH functional description 1183
33.4.1 HASH block diagram 1183
33.4.2 HASH internal signals 1183
33.4.3 About secure hash algorithms 1184
33.4.4 Message data feeding 1184
33.4.5 Message digest computing 1185
33.4.6 Message padding 1187
33.4.7 HMAC operation 1188
33.4.8 HASH suspend/resume operations 1190
33.4.9 HASH DMA interface 1192
33.4.10 HASH error management 1193
33.4.11 HASH processing time 1193
33.5 HASH interrupts 1194
33.6 HASH registers 1194
33.6.1 HASH control register (HASH_CR) 1194
33.6.2 HASH data input register (HASH_DIN) 1196
33.6.3 HASH start register (HASH_STR) 1197
33.6.4 HASH digest registers 1198
33.6.5 HASH interrupt enable register (HASH_IMR) 1200
33.6.6 HASH status register (HASH_SR) 1200

34 Public key accelerator (PKA) 1204
34.1 PKA introduction 1204
34.2 PKA main features 1204
34.3 PKA implementation 1204
34.4 PKA functional description 1205
34.4.1 PKA block diagram 1205
34.4.2 PKA internal signals 1205
34.4.3 PKA reset and clocks 1206
34.4.4 PKA public key acceleration 1206
34.4.5 Typical applications for PKA 1208

34.4.6 PKA procedure to perform an operation 1210
34.4.7 Private keys protection using CCB 1211
34.4.8 PKA error management 1215
34.5 PKA operating modes 1215
34.5.1 Introduction 1215
34.5.2 Montgomery parameter computation 1217
34.5.3 Modular addition 1217
34.5.4 Modular subtraction 1217
34.5.5 Modular and Montgomery multiplication 1218
34.5.6 Modular exponentiation 1219
34.5.7 Modular inversion 1220
34.5.8 Modular reduction 1221
34.5.9 Arithmetic addition 1221
34.5.10 Arithmetic subtraction 1221
34.5.11 Arithmetic multiplication 1222
34.5.12 Arithmetic comparison 1222
34.5.13 RSA CRT exponentiation 1223
34.5.14 Point on elliptic curve Fp check 1223
34.5.15 ECC Fp scalar multiplication 1224
34.5.16 ECDSA sign 1225
34.5.17 ECDSA verification 1227
34.5.18 ECC complete addition 1228
34.5.19 ECC double base ladder 1228
34.5.20 ECC projective to affine 1229
34.6 Example of configurations and processing times 1230
34.6.1 Supported elliptic curves 1230
34.6.2 Computation times 1232
34.7 PKA interrupts 1234
34.8 PKA registers 1235
34.8.1 PKA control register (PKA_CR) 1235
34.8.2 PKA status register (PKA_SR) 1237
34.8.3 PKA clear flag register (PKA_CLRFR) 1239
34.8.4 PKA RAM 1240
34.8.5 PKA register map 1241

35 Advanced-control timers (TIM1) 1242

35.1 TIM1 introduction 1242

35.2 TIM1 main features 1243
35.3 TIM1 functional description 1244
35.3.1 Block diagram 1244
35.3.2 TIM1 pins and internal signals 1245
35.3.3 Time-base unit 1249
35.3.4 Counter modes 1251
35.3.5 Repetition counter 1263
35.3.6 External trigger input 1264
35.3.7 Clock selection 1265
35.3.8 Capture/compare channels 1269
35.3.9 Input capture mode 1272
35.3.10 PWM input mode 1273
35.3.11 Forced output mode 1274
35.3.12 Output compare mode 1274
35.3.13 PWM mode 1276
35.3.14 Asymmetric PWM mode 1284
35.3.15 Combined PWM mode 1285
35.3.16 Combined 3-phase PWM mode 1286
35.3.17 Complementary outputs and dead-time insertion 1287
35.3.18 Using the break function 1290
35.3.19 Bidirectional break inputs 1296
35.3.20 Clearing the tim_ocxref signal on an external event 1297
35.3.21 6-step PWM generation 1299
35.3.22 One-pulse mode 1300
35.3.23 Retriggerable One-pulse mode 1302
35.3.24 Pulse on compare mode 1303
35.3.25 Encoder interface mode 1305
35.3.26 Direction bit output 1322
35.3.27 UIF bit remapping 1323
35.3.28 Timer input XOR function 1323
35.3.29 Interfacing with Hall sensors 1323
35.3.30 Timer synchronization 1325
35.3.31 ADC triggers 1330
35.3.32 ADC synchronization 1330
35.3.33 DMA burst mode 1331
35.3.34 TIM1 DMA requests 1332
35.3.35 Debug mode 1332

35.4 TIM1 low-power modes 1333
35.5 TIM1 interrupts 1333
35.6 TIM1 registers 1334
35.6.1 TIM1 control register 1 (TIM1_CR1) 1334
35.6.2 TIM1 control register 2 (TIM1_CR2) 1335
35.6.3 TIM1 slave mode control register (TIM1_SMCR) 1339
35.6.4 TIM1 DMA/interrupt enable register (TIM1_DIER) 1343
35.6.5 TIM1 status register (TIM1_SR) 1344
35.6.6 TIM1 event generation register (TIM1_EGR) 1347
35.6.7 TIM1 capture/compare mode register 1 (TIM1_CCMR1) 1348
35.6.8 TIM1 capture/compare mode register 1 [alternate] (TIM1_CCMR1) 1350
35.6.9 TIM1 capture/compare mode register 2 (TIM1_CCMR2) 1353
35.6.10 TIM1 capture/compare mode register 2 [alternate] (TIM1_CCMR2) 1354
35.6.11 TIM1 capture/compare enable register (TIM1_CCER) 1357
35.6.12 TIM1 counter (TIM1_CNT) 1361
35.6.13 TIM1 prescaler (TIM1_PSC) 1361
35.6.14 TIM1 autoreload register (TIM1_ARR) 1362
35.6.15 TIM1 repetition counter register (TIM1_RCR) 1362
35.6.16 TIM1 capture/compare register 1 (TIM1_CCR1) 1363
35.6.17 TIM1 capture/compare register 2 (TIM1_CCR2) 1363
35.6.18 TIM1 capture/compare register 3 (TIM1_CCR3) 1364
35.6.19 TIM1 capture/compare register 4 (TIM1_CCR4) 1365
35.6.20 TIM1 break and dead-time register (TIM1_BDTR) 1366
35.6.21 TIM1 capture/compare register 5 (TIM1_CCR5) 1370
35.6.22 TIM1 capture/compare register 6 (TIM1_CCR6) 1371
35.6.23 TIM1 capture/compare mode register 3 (TIM1_CCMR3) 1372
35.6.24 TIM1 timer deadtime register 2 (TIM1_DTR2) 1373
35.6.25 TIM1 timer encoder control register (TIM1_ECR) 1374
35.6.26 TIM1 timer input selection register (TIM1_TISEL) 1375
35.6.27 TIM1 alternate function option register 1 (TIM1_AF1) 1376
35.6.28 TIM1 alternate function register 2 (TIM1_AF2) 1379
35.6.29 TIM1 DMA control register (TIM1_DCR) 1381
35.6.30 TIM1 DMA address for full transfer (TIM1_DMAR) 1383
35.6.31 TIM1 register map 1383

36 General-purpose timers (TIM2/TIM3/TIM4) 1386

36.1 TIM2/TIM3/TIM4 introduction 1386

36.2 TIM2/TIM3/TIM4 main features 1386

36.3 TIM2/TIM3/TIM4 implementation 1387

36.4 TIM2/TIM3/TIM4 functional description 1388

36.4.2 TIM2/TIM3/TIM4 pins and internal signals 1389

36.4.3 Time-base unit 1392

36.4.4 Counter modes 1394

36.4.5 Clock selection 1406

36.4.6 Capture/compare channels 1410

36.4.7 Input capture mode 1412

36.4.8 PWM input mode 1413

36.4.9 Forced output mode 1414

36.4.10 Output compare mode 1414

36.4.11 PWM mode 1416

36.4.12 Asymmetric PWM mode 1424

36.4.13 Combined PWM mode 1425

36.4.14 Clearing the tim_ocxref signal on an external event 1426

36.4.15 One-pulse mode 1428

36.4.16 Retriggerable one-pulse mode 1429

36.4.17 Pulse on compare mode 1430

36.4.18 Encoder interface mode 1432

36.4.19 Direction bit output 1450

36.4.20 UIF bit remapping 1451

36.4.21 Timer input XOR function 1451

36.4.22 Timers and external trigger synchronization 1451

36.4.23 Timer synchronization 1455

36.4.24 ADC triggers 1460

36.4.25 ADC synchronization 1462

36.4.26 DMA burst mode 1462

36.4.27 TIM2/TIM3/TIM4 DMA requests 1463

36.4.28 Debug mode 1464

36.4.29 TIM2/TIM3/TIM4 low-power modes 1464

36.4.30 TIM2/TIM3/TIM4 interrupts 1465

36.5 TIM2/TIM3/TIM4 registers 1466

36.5.1 TIMx control register 1 (TIMx_CR1)(x = 2 to 4) 1466
36.5.2 TIMx control register 2 (TIMx_CR2)(x = 2 to 4) 1467
36.5.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 4) 1469
36.5.4 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 2 to 4) 1473
36.5.5 TIMx status register (TIMx_SR)(x = 2 to 4) 1474
36.5.6 TIMx event generation register (TIMx_EGR)(x = 2 to 4) 1476
36.5.7 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 2 to 4) . 1477
36.5.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 2 to 4) 1479
36.5.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 2 to 4) . 1481
36.5.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 2 to 4) 1482
36.5.11 TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 4) . . . 1485
36.5.12 TIMx counter (TIMx_CNT)(x = 2 to 4) 1487
36.5.13 TIMx prescaler (TIMx_PSC)(x = 2 to 4) 1487
36.5.14 TIMx autoreload register (TIMx_ARR)(x = 2 to 4) 1488
36.5.15 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 4) 1488
36.5.16 TIMx capture/compare register 2 (TIMx_CCR2)(x = 2 to 4) 1489
36.5.17 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2 to 4) 1490
36.5.18 TIMx capture/compare register 4 (TIMx_CCR4)(x = 2 to 4) 1491
36.5.19 TIMx timer encoder control register (TIMx_ECR)(x = 2 to 4) 1492
36.5.20 TIMx timer input selection register (TIMx_TISEL)(x = 2 to 4) 1493
36.5.21 TIMx alternate function register 1 (TIMx_AF1)(x = 2 to 4) 1494
36.5.22 TIMx alternate function register 2 (TIMx_AF2)(x = 2 to 4) 1495
36.5.23 TIMx DMA control register (TIMx_DCR)(x = 2 to 4) 1496
36.5.24 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 4) 1497
36.5.25 TIMx register map 1498

37 Basic timers (TIM6/TIM7) 1501

39.7.3 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) (x = 1 to 3) 1659
39.7.4 LPTIM4 interrupt clear register (LPTIM4_ICR) 1661
39.7.5 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR) (x = 1 to 3) 1662
39.7.6 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR) (x = 1 to 3) 1663
39.7.7 LPTIM4 interrupt enable register (LPTIM4_DIER) 1664

39.7.8 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3) 1666
39.7.9 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3) 1667
39.7.10 LPTIM configuration register (LPTIM_CFGR) 1669
39.7.11 LPTIM control register (LPTIM_CR) 1672
39.7.12 LPTIM compare register 1 (LPTIM_CCR1) 1673
39.7.13 LPTIM autoreload register (LPTIM_ARR) 1674
39.7.14 LPTIM counter register (LPTIM_CNT) 1674
39.7.15 LPTIM configuration register 2 (LPTIM_CFGR2) 1675
39.7.16 LPTIM repetition register (LPTIM_RCR) 1676
39.7.17 LPTIM capture/compare mode register 1 (LPTIM_CCMR1) 1676
39.7.18 LPTIM compare register 2 (LPTIM_CCR2) 1679
39.7.19 LPTIM register map 1679

40 Infrared interface (IRTIM) 1682

41 Independent watchdog (IWDG) 1683

41.1 Introduction 1683
41.2 IWDG main features 1683
41.3 IWDG implementation 1684
41.4 IWDG functional description 1684
41.4.1 IWDG block diagram 1684
41.4.2 IWDG internal signals 1685
41.4.3 Software and hardware watchdog modes 1686
41.4.4 Window option 1687
41.4.5 Debug 1690
41.4.6 Register access protection 1690
41.5 IWDG low power modes 1690
41.6 IWDG interrupts 1691
41.7 IWDG registers 1692
41.7.1 IWDG key register (IWDG_KR) 1692
41.7.2 IWDG prescaler register (IWDG_PR) 1693
41.7.3 IWDG reload register (IWDG_RLR) 1694
41.7.4 IWDG status register (IWDG_SR) 1694
41.7.5 IWDG window register (IWDG_WINR) 1695
41.7.6 IWDG early wake-up interrupt register (IWDG_EWCR) 1696

41.7.7 IWDG register map 1697

42 System window watchdog (WWDG) 1698

42.1 Introduction 1698
42.2 WWDG main features 1698
42.3 WWDG implementation 1698
42.4 WWDG functional description 1699
42.4.1 WWDG block diagram 1699
42.4.2 WWDG internal signals 1699
42.4.3 Enabling the watchdog 1700
42.4.4 Controlling the down-counter 1700
42.4.5 How to program the watchdog timeout 1700
42.4.6 Debug mode 1701
42.5 WWDG interrupts 1702
42.6 WWDG registers 1702
42.6.1 WWDG control register (WWDG_CR) 1702
42.6.2 WWDG configuration register (WWDG_CFR) 1703
42.6.3 WWDG status register (WWDG_SR) 1704
42.6.4 WWDG register map 1704

43 Real-time clock (RTC) 1705

43.1 Introduction 1705
43.2 RTC main features 1705
43.3 RTC functional description 1706
43.3.1 RTC block diagram 1706
43.3.2 RTC pins and internal signals 1708
43.3.3 GPIOs controlled by the RTC 1709
43.3.4 RTC secure protection modes 1709
43.3.5 RTC privilege protection modes 1711
43.3.6 Clock and prescalers 1712
43.3.7 Real-time clock and calendar 1713
43.3.8 Calendar ultra-low power mode 1714
43.3.9 Programmable alarms 1714
43.3.10 Periodic auto-wake-up 1714
43.3.11 RTC initialization and configuration 1715
43.3.12 Reading the calendar 1718

43.3.13 Resetting the RTC . . . 1719
43.3.14 RTC synchronization . . . 1719
43.3.15 RTC reference clock detection . . . 1720
43.3.16 RTC smooth digital calibration . . . 1721
43.3.17 Timestamp function . . . 1723
43.3.18 Calibration clock output . . . 1724
43.3.19 Tamper and alarm output . . . 1724
43.4 RTC low-power modes . . . 1725
43.5 RTC interrupts . . . 1725
43.6 RTC registers . . . 1727
43.6.1 RTC time register (RTC_TR) . . . 1727
43.6.2 RTC date register (RTC_DR) . . . 1728
43.6.3 RTC subsecond register (RTC_SSR) . . . 1729
43.6.4 RTC initialization control and status register (RTC_ICSR) . . . 1730
43.6.5 RTC prescaler register (RTC_PRER) . . . 1732
43.6.6 RTC wake-up timer register (RTC_WUTR) . . . 1733
43.6.7 RTC control register (RTC_CR) . . . 1734
43.6.8 RTC privilege mode control register (RTC_PRIVCFGR) . . . 1738
43.6.9 RTC secure configuration register (RTC_SECCFGR) . . . 1739
43.6.10 RTC write protection register (RTC_WPR) . . . 1740
43.6.11 RTC calibration register (RTC_CALR) . . . 1741
43.6.12 RTC shift control register (RTC_SHIFTR) . . . 1742
43.6.13 RTC timestamp time register (RTC_TSTR) . . . 1743
43.6.14 RTC timestamp date register (RTC_TSDR) . . . 1744
43.6.15 RTC timestamp subsecond register (RTC_TSSSR) . . . 1745
43.6.16 RTC alarm A register (RTC_ALRMAR) . . . 1745
43.6.17 RTC alarm A subsecond register (RTC_ALRMASSR) . . . 1747
43.6.18 RTC alarm B register (RTC_ALRMBR) . . . 1748
43.6.19 RTC alarm B subsecond register (RTC_ALRMBSSR) . . . 1749
43.6.20 RTC status register (RTC_SR) . . . 1750
43.6.21 RTC nonsecure masked interrupt status register (RTC_MISR) . . . 1751
43.6.22 RTC secure masked interrupt status register (RTC_SMISR) . . . 1752
43.6.23 RTC status clear register (RTC_SCR) . . . 1754
43.6.24 RTC timestamp on tamper control register (RTC_TAMPTSCR) . . . 1755
43.6.25 RTC timestamp status register (RTC_TSIDR) . . . 1756
43.6.26 RTC alarm A binary mode register (RTC_ALRABINR) . . . 1757
43.6.27 RTC alarm B binary mode register (RTC_ALRBBINR) . . . 1757

43.6.28 RTC register map 1759

44 Tamper and backup registers (TAMP) 1762

44.1 Introduction 1762

44.2 TAMP main features 1762

44.3 TAMP functional description 1763

44.3.1 TAMP block diagram 1763

44.3.2 TAMP pins and internal signals 1764

44.3.3 GPIOs controlled by the RTC and TAMP 1766

44.3.4 TAMP register write protection 1768

44.3.5 TAMP secure protection modes 1768

44.3.6 Backup registers protection zones 1768

44.3.7 TAMP privilege protection modes 1769

44.3.8 Boot hardware key (BHK) 1769

44.3.9 Tamper detection 1769

44.3.10 TAMP backup registers and other device secrets erase 1770

44.3.11 Tamper detection - confirmed mode 1770

44.3.12 Tamper detection configuration and initialization 1772

44.4 TAMP in low-power modes 1775

44.5 TAMP interrupts 1775

44.6 TAMP registers 1776

44.6.1 TAMP control register 1 (TAMP_CR1) 1776

44.6.2 TAMP control register 2 (TAMP_CR2) 1777

44.6.3 TAMP control register 3 (TAMP_CR3) 1778

44.6.4 TAMP filter control register (TAMP_FLTCR) 1779

44.6.5 TAMP secure configuration register (TAMP_SECCFGR) 1780

44.6.6 TAMP privileged configuration register (TAMP_PRIVCFGR) 1782

44.6.7 TAMP interrupt enable register (TAMP_IER) 1783

44.6.8 TAMP status register (TAMP_SR) 1784

44.6.9 TAMP nonsecure masked interrupt status register (TAMP_MISR) . . 1785

44.6.10 TAMP secure masked interrupt status register (TAMP_SMISR) 1786

44.6.11 TAMP status clear register (TAMP_SCR) 1787

44.6.12 TAMP monotonic counter 1 register (TAMP_COUNT1R) 1788

44.6.13 TAMP resource protection register (TAMP_RPCFGR) 1788

44.6.14 TAMP backup x register (TAMP_BKPxR) 1789

44.6.15 TAMP register map 1789

45 Inter-integrated circuit interface (I2C) 1792

45.1 Introduction 1792

45.2 I2C main features 1792

45.3 I2C implementation 1793

45.4 I2C functional description 1793

45.4.1 I2C block diagram 1794

45.4.2 I2C pins and internal signals 1794

45.4.3 I2C clock requirements 1795

45.4.4 I2C mode selection 1796

45.4.5 I2C initialization 1797

45.4.6 I2C reset 1801

45.4.7 I2C data transfer 1801

45.4.8 I2C target mode 1803

45.4.9 I2C controller mode 1812

45.4.10 I2C_TIMINGR register configuration examples 1823

45.4.11 SMBus specific features 1825

45.4.12 SMBus initialization 1828

45.4.13 SMBus I2C_TIMEOUTR register configuration examples 1830

45.4.14 SMBus target mode 1830

45.4.15 SMBus controller mode 1834

45.4.16 Autonomous mode 1837

45.4.17 Error conditions 1839

45.5 I2C in low-power modes 1840

45.6 I2C interrupts 1841

45.7 I2C DMA requests 1841

45.7.1 Transmission using DMA 1841

45.7.2 Reception using DMA 1842

45.7.3 Controller event control using DMA 1842

45.8 I2C debug modes 1843

45.9 I2C registers 1843

45.9.1 I2C control register 1 (I2C_CR1) 1843

45.9.2 I2C control register 2 (I2C_CR2) 1846

45.9.3 I2C own address 1 register (I2C_OAR1) 1848

45.9.4 I2C own address 2 register (I2C_OAR2) 1848

45.9.5 I2C timing register (I2C_TIMINGR) 1849

45.9.6 I2C timeout register (I2C_TIMEOUTR) 1850

45.9.7 I2C interrupt and status register (I2C_ISR) . . . 1851
45.9.8 I2C interrupt clear register (I2C_ICR) . . . 1854
45.9.9 I2C PEC register (I2C_PECR) . . . 1855
45.9.10 I2C receive data register (I2C_RXDR) . . . 1855
45.9.11 I2C transmit data register (I2C_TXDR) . . . 1856
45.9.12 I2C autonomous mode control register (I2C_AUTOCR) . . . 1856
45.9.13 I2C register map . . . 1858

46 Improved inter-integrated circuit (I3C) . . . 1860

46.1 Introduction . . . 1860
46.2 I3C main features . . . 1860
46.3 I3C implementation . . . 1862
46.3.1 I3C instantiation . . . 1862
46.3.2 I3C wake-up from low-power mode(s) . . . 1862
46.3.3 I3C autonomous mode with DMA in Stop mode(s) . . . 1862
46.3.4 I3C FIFOs . . . 1862
46.3.5 I3C triggers . . . 1863
46.3.6 I3C interrupt(s) . . . 1863
46.3.7 I3C MIPI® support . . . 1864
46.4 I3C block diagram . . . 1865
46.5 I3C pins and internal signals . . . 1865
46.6 I3C reset and clocks . . . 1866
46.6.1 I3C reset . . . 1866
46.6.2 I3C clocks and requirements . . . 1866
46.7 I3C peripheral state and programming . . . 1868
46.7.1 I3C peripheral state . . . 1868
46.7.2 I3C controller state and programming sequence . . . 1869
46.7.3 I3C target state and programming sequence . . . 1873
46.8 I3C registers and programming . . . 1877
46.8.1 I3C register set, as controller/target . . . 1877
46.8.2 I3C registers and fields use versus peripheral state, as controller . . . 1878
46.8.3 I3C registers and fields usage versus peripheral state, as target . . . 1881
46.9 I3C bus transfers and programming . . . 1883
46.9.1 I3C command set (CCCs), as controller/target . . . 1883
46.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller . . . 1887

46.9.3 I3C broadcast ENTDAA CCC transfer, as controller 1889
46.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller 1889
46.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target 1891
46.9.6 I3C broadcast ENTDAA CCC transfer, as target 1893
46.9.7 I3C broadcast DEFTGTS CCC transfer, as target 1894
46.9.8 I3C broadcast DEFGRPA CCC transfer, as target 1895
46.9.9 I3C direct GETSTATUS CCC response, as target 1896
46.9.10 I3C private read/write transfer, as controller 1897
46.9.11 I3C private read/write transfer, as target 1898
46.9.12 Legacy I2C read/write transfer, as controller 1899
46.9.13 I3C IBI transfer, as controller/target 1900
46.9.14 I3C hot-join request transfer, as controller/target 1902
46.9.15 I3C controller-role request transfer, as controller/target 1903
46.10 I3C FIFOs management, as controller 1904
46.10.1 C-FIFO management, as controller 1904
46.10.2 TX-FIFO management, as controller 1905
46.10.3 RX-FIFO management, as controller 1908
46.10.4 S-FIFO management, as controller 1910
46.11 I3C FIFOs management, as target 1912
46.11.1 RX-FIFO management, as target 1912
46.11.2 TX-FIFO management, as target 1913
46.12 I3C error management 1916
46.12.1 Controller error management 1916
46.12.2 Target error management 1918
46.13 I3C wake-up from low-power mode(s) 1919
46.13.1 Wake-up from Stop 1919
46.13.2 52.13.1 I3C wake-up from Standby 1922
46.14 I3C in low-power modes 1922
46.15 I3C interrupts 1923
46.16 I3C registers 1924
46.16.1 I3C message control register (I3C_CR) 1924
46.16.2 I3C message control register [alternate] (I3C_CR) 1926
46.16.3 I3C configuration register (I3C_CFGR) 1928
46.16.4 I3C receive data byte register (I3C_RDR) 1933
46.16.5 I3C receive data word register (I3C_RDWR) 1934

46.16.6 I3C transmit data byte register (I3C_TDR) 1935
46.16.7 I3C transmit data word register (I3C_TDWR) 1936
46.16.8 I3C IBI payload data register (I3C_IBIDR) 1938
46.16.9 I3C target transmit configuration register (I3C_TGTTDR) 1939
46.16.10 I3C status register (I3C_SR) 1940
46.16.11 I3C status error register (I3C_SER) 1941
46.16.12 I3C received message register (I3C_RMR) 1943
46.16.13 I3C event register (I3C_EVR) 1944
46.16.14 I3C interrupt enable register (I3C_IER) 1948
46.16.15 I3C clear event register (I3C_CEVR) 1950
46.16.16 I3C masked interrupt status register (I3C_MISR) 1952
46.16.17 I3C own device characteristics register (I3C_DEVR0) 1953
46.16.18 I3C device x characteristics register (I3C_DEVRx) 1955
46.16.19 I3C maximum read length register (I3C_MAXRLR) 1957
46.16.20 I3C maximum write length register (I3C_MAXWLR) 1958
46.16.21 I3C timing register 0 (I3C_TIMINGR0) 1959
46.16.22 I3C timing register 1 (I3C_TIMINGR1) 1960
46.16.23 I3C timing register 2 (I3C_TIMINGR2) 1962
46.16.24 I3C bus characteristics register (I3C_BCR) 1963
46.16.25 I3C device characteristics register (I3C_DCR) 1964
46.16.26 I3C get capability register (I3C_GETCAPR) 1965
46.16.27 I3C controller-role capability register (I3C_CRCAPR) 1966
46.16.28 I3C get max data speed register (I3C_GETMXDSR) 1967
46.16.29 I3C extended provisioned ID register (I3C_EPIDR) 1969
46.16.30 I3C register map 1970

47 Universal synchronous/asynchronous receiver transmitter (USART/UART) 1973

47.1 Introduction 1973
47.2 USART main features 1973
47.3 USART extended features 1974
47.4 USART implementation 1974
47.5 USART functional description 1976
47.5.1 USART block diagram 1976
47.5.2 USART pins and internal signals 1976
47.5.3 USART clocks 1979
47.5.4 USART character description 1979

47.5.5 USART FIFOs and thresholds . . . 1981
47.5.6 USART transmitter . . . 1981
47.5.7 USART receiver . . . 1984
47.5.8 USART baud rate generation . . . 1991
47.5.9 Tolerance of the USART receiver to clock deviation . . . 1993
47.5.10 USART auto baud rate detection . . . 1994
47.5.11 USART multiprocessor communication . . . 1996
47.5.12 USART Modbus communication . . . 1998
47.5.13 USART parity control . . . 1999
47.5.14 USART LIN (local interconnection network) mode . . . 2000
47.5.15 USART synchronous mode . . . 2002
47.5.16 USART single-wire half-duplex communication . . . 2006
47.5.17 USART receiver timeout . . . 2006
47.5.18 USART smartcard mode . . . 2007
47.5.19 USART IrDA SIR ENDEC block . . . 2011
47.5.20 Continuous communication using USART and DMA . . . 2014
47.5.21 RS232 hardware flow control and RS485 driver enable . . . 2016
47.5.22 USART autonomous mode . . . 2018
47.6 USART in low-power modes . . . 2020
47.7 USART interrupts . . . 2020
47.8 USART registers . . . 2023
47.8.1 USART control register 1 (USART_CR1) . . . 2023
47.8.2 USART control register 1 [alternate] (USART_CR1) . . . 2027
47.8.3 USART control register 2 (USART_CR2) . . . 2030
47.8.4 USART control register 3 (USART_CR3) . . . 2034
47.8.5 USART control register 3 [alternate] (USART_CR3) . . . 2038
47.8.6 USART baud rate register (USART_BRR) . . . 2041
47.8.7 USART guard time and prescaler register (USART_GTPR) . . . 2042
47.8.8 USART receiver timeout register (USART_RTOR) . . . 2043
47.8.9 USART request register (USART_RQR) . . . 2044
47.8.10 USART interrupt and status register (USART_ISR) . . . 2045
47.8.11 USART interrupt and status register [alternate] (USART_ISR) . . . 2051
47.8.12 USART interrupt flag clear register (USART_ICR) . . . 2056
47.8.13 USART receive data register (USART_RDR) . . . 2057
47.8.14 USART transmit data register (USART_TDR) . . . 2058
47.8.15 USART prescaler register (USART_PRESC) . . . 2058
47.8.16 USART autonomous mode control register (USART_AUTOCR) . . . 2059

47.8.17 USART register map 2060

48 Low-power universal asynchronous receiver transmitter (LPUART) 2062

48.1 Introduction 2062
48.2 LPUART main features 2062
48.3 LPUART implementation 2063
48.4 LPUART functional description 2064
48.4.1 LPUART block diagram 2064
48.4.2 LPUART pins and internal signals 2065
48.4.3 LPUART clocks 2067
48.4.4 LPUART character description 2067
48.4.5 LPUART FIFOs and thresholds 2069
48.4.6 LPUART transmitter 2069
48.4.7 LPUART receiver 2073
48.4.8 LPUART baud rate generation 2077
48.4.9 Tolerance of the LPUART receiver to clock deviation 2078
48.4.10 LPUART multiprocessor communication 2079
48.4.11 LPUART parity control 2081
48.4.12 LPUART single-wire half-duplex communication 2082
48.4.13 Continuous communication using DMA and LPUART 2082
48.4.14 RS232 hardware flow control and RS485 driver enable 2085
48.4.15 LPUART autonomous mode 2087
48.5 LPUART in low-power modes 2089
48.6 LPUART interrupts 2090
48.7 LPUART registers 2091
48.7.1 LPUART control register 1 (LPUART_CR1) 2091
48.7.2 LPUART control register 1 [alternate] (LPUART_CR1) 2094
48.7.3 LPUART control register 2 (LPUART_CR2) 2097
48.7.4 LPUART control register 3 (LPUART_CR3) 2099
48.7.5 LPUART control register 3 [alternate] (LPUART_CR3) 2101
48.7.6 LPUART baud rate register (LPUART_BRR) 2103
48.7.7 LPUART request register (LPUART_RQR) 2103
48.7.8 LPUART interrupt and status register (LPUART_ISR) 2104
48.7.9 LPUART interrupt and status register [alternate] (LPUART_ISR) . . . 2109
48.7.10 LPUART interrupt flag clear register (LPUART_ICR) 2112

48.7.11 LPUART receive data register (LPUART_RDR) 2113
48.7.12 LPUART transmit data register (LPUART_TDR) 2113
48.7.13 LPUART prescaler register (LPUART_PRESC) 2114
48.7.14 LPUART autonomous mode control register (LPUART_AUTOCR) . . 2115
48.7.15 LPUART register map 2115

49 Serial peripheral interface (SPI) 2118

49.1 Introduction 2118
49.2 SPI main features 2118
49.3 SPI implementation 2119
49.4 SPI functional description 2120
49.4.1 SPI block diagram 2120
49.4.2 SPI pins and internal signals 2121
49.4.3 SPI communication general aspects 2123
49.4.4 Communications between one master and one slave 2123
49.4.5 Standard multislave communication 2126
49.4.6 Multimaster communication 2127
49.4.7 Slave select (NSS pin) management 2128
49.4.8 Ready pin (RDY) management 2132
49.4.9 Communication formats 2132
49.4.10 Configuring the SPI 2134
49.4.11 Enabling the SPI 2135
49.4.12 SPI data transmission and reception procedures 2136
49.4.13 Disabling the SPI 2140
49.4.14 Communication using DMA (direct memory addressing) 2141
49.4.15 Autonomous mode 2142
49.5 SPI specific modes and control 2144
49.5.1 TI mode 2144
49.5.2 SPI error flags 2145
49.5.3 CRC computation 2148
49.6 SPI in low-power modes 2149
49.7 SPI interrupts 2149
49.8 SPI registers 2151
49.8.1 SPI control register 1 (SPI_CR1) 2151
49.8.2 SPI control register 2 (SPI_CR2) 2153
49.8.3 SPI configuration register 1 (SPI_CFG1) 2153

49.8.4 SPI configuration register 2 (SPI_CFG2) 2156
49.8.5 SPI interrupt enable register (SPI_IER) 2158
49.8.6 SPI status register (SPI_SR) 2159
49.8.7 SPI interrupt/status flags clear register (SPI_IFCR) 2162
49.8.8 SPI autonomous mode control register (SPI_AUTOCR) 2163
49.8.9 SPI transmit data register (SPI_TXDR) 2163
49.8.10 SPI receive data register (SPI_RXDR) 2164
49.8.11 SPI polynomial register (SPI_CRCPOLY) 2164
49.8.12 SPI transmitter CRC register (SPI_TXCRC) 2165
49.8.13 SPI receiver CRC register (SPI_RXCRC) 2166
49.8.14 SPI underrun data register (SPI_UDRDR) 2166
49.8.15 SPI register map 2167

50 Serial audio interface (SAI) 2168

50.1 Introduction 2168
50.2 SAI main features 2168
50.3 SAI implementation 2169
50.4 SAI functional description 2170
50.4.1 SAI block diagram 2170
50.4.2 SAI pins and internal signals 2171
50.4.3 Main SAI modes 2171
50.4.4 SAI synchronization mode 2172
50.4.5 Audio data size 2173
50.4.6 Frame synchronization 2173
50.4.7 Slot configuration 2176
50.4.8 SAI clock generator 2178
50.4.9 Internal FIFOs 2181
50.4.10 PDM interface 2183
50.4.11 AC’97 link controller 2191
50.4.12 SPDIF output 2192
50.4.13 Specific features 2195
50.4.14 Error flags 2199
50.4.15 Disabling the SAI 2202
50.4.16 SAI DMA interface 2202
50.5 SAI interrupts 2203
50.6 SAI registers 2205

50.6.1 SAI configuration register 1 (SAI_ACR1) 2205
50.6.2 SAI configuration register 2 (SAI_ACR2) 2207
50.6.3 SAI frame configuration register (SAI_AFRCR) 2209
50.6.4 SAI slot register (SAI_ASLOTR) 2210
50.6.5 SAI interrupt mask register (SAI_AIM) 2211
50.6.6 SAI status register (SAI_ASR) 2213
50.6.7 SAI clear flag register (SAI_ACLRFR) 2215
50.6.8 SAI data register (SAI_ADR) 2216
50.6.9 SAI configuration register 1 (SAI_BCR1) 2216
50.6.10 SAI configuration register 2 (SAI_BCR2) 2219
50.6.11 SAI frame configuration register (SAI_BFRCR) 2221
50.6.12 SAI slot register (SAI_BSLOTR) 2222
50.6.13 SAI interrupt mask register (SAI_BIM) 2223
50.6.14 SAI status register (SAI_BSR) 2224
50.6.15 SAI clear flag register (SAI_BCLRFR) 2226
50.6.16 SAI data register (SAI_BDR) 2227
50.6.17 SAI PDM control register (SAI_PDMCR) 2228
50.6.18 SAI PDM delay register (SAI_PDMDLY) 2229
50.6.19 SAI register map 2231

51 FD controller area network (FDCAN) 2233

51.1 Introduction 2233
51.2 FDCAN main features 2235
51.3 FDCAN functional description 2236
51.3.1 FDCAN block diagram 2236
51.3.2 FDCAN pins and internal signals 2237
51.3.3 Bit timing 2238
51.3.4 Operating modes 2239
51.3.5 Error management 2248
51.3.6 Message RAM 2249
51.3.7 FIFO acknowledge handling 2258
51.3.8 FDCAN Rx FIFO element 2258
51.3.9 FDCAN Tx buffer element 2260
51.3.10 FDCAN Tx event FIFO element 2262
51.3.11 FDCAN standard message ID filter element 2263
51.3.12 FDCAN extended message ID filter element 2264
51.4 FDCAN registers 2266

51.4.1 FDCAN core release register (FDCAN_CREL) 2266
51.4.2 FDCAN endian register (FDCAN_ENDN) 2266
51.4.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP) 2266
51.4.4 FDCAN test register (FDCAN_TEST) 2267
51.4.5 FDCAN RAM watchdog register (FDCAN_RWD) 2268
51.4.6 FDCAN CC control register (FDCAN_CCCR) 2269
51.4.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) . 2270
51.4.8 FDCAN timestamp counter configuration register (FDCAN_TSCC) . 2272
51.4.9 FDCAN timestamp counter value register (FDCAN_TSCV) 2272
51.4.10 FDCAN timeout counter configuration register (FDCAN_TOCC) . . . 2273
51.4.11 FDCAN timeout counter value register (FDCAN_TOCV) 2274
51.4.12 FDCAN error counter register (FDCAN_ECR) 2274
51.4.13 FDCAN protocol status register (FDCAN_PSR) 2275
51.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR) . . 2277
51.4.15 FDCAN interrupt register (FDCAN_IR) 2277
51.4.16 FDCAN interrupt enable register (FDCAN_IE) 2280
51.4.17 FDCAN interrupt line select register (FDCAN_ILS) 2282
51.4.18 FDCAN interrupt line enable register (FDCAN_ILE) 2283
51.4.19 FDCAN global filter configuration register (FDCAN_RXGFC) 2283
51.4.20 FDCAN extended ID and mask register (FDCAN_XIDAM) 2285
51.4.21 FDCAN high-priority message status register (FDCAN_HPMS) 2285
51.4.22 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S) 2286
51.4.23 CAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A) 2287
51.4.24 FDCAN Rx FIFO 1 status register (FDCAN_RXF1S) 2287
51.4.25 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) 2288
51.4.26 FDCAN Tx buffer configuration register (FDCAN_TXBC) 2288
51.4.27 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS) 2289
51.4.28 FDCAN Tx buffer request pending register (FDCAN_TXBRP) 2289
51.4.29 FDCAN Tx buffer add request register (FDCAN_TXBAR) 2290
51.4.30 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR) . . 2291
51.4.31 FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO) 2291
51.4.32 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF) . . 2292
51.4.33 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE) 2292
51.4.34 FDCAN Tx buffer cancellation finished interrupt enable register (FDCAN_TXBCIE) 2293
51.4.35 FDCAN Tx event FIFO status register (FDCAN_TXEFS) 2293
51.4.36 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA) . . . 2294

51.4.37 FDCAN CFG clock divider register (FDCAN_CKDIV) 2294
51.4.38 FDCAN register map 2295

52 Universal serial bus full-speed host/device interface (USB) 2299

52.1 Introduction 2299
52.2 USB main features 2299
52.3 USB implementation 2299
52.4 USB functional description 2300
52.4.1 USB block diagram 2300
52.4.2 USB pins and internal signals 2300
52.4.3 USB reset and clocks 2301
52.4.4 General description and Device mode functionality 2301
52.4.5 Description of USB blocks used in both Device and Host modes . . . 2302
52.4.6 Description of host frame scheduler (HFS) specific to Host mode . . 2303
52.5 Programming considerations for Device and Host modes 2304
52.5.1 Generic USB Device programming 2304
52.5.2 System and power-on reset 2305
52.5.3 Double-buffered endpoints and usage in Device mode 2312
52.5.4 Double buffered channels: usage in Host mode 2314
52.5.5 Isochronous transfers in Device mode 2315
52.5.6 Isochronous transfers in Host mode 2316
52.5.7 Suspend/resume events 2317
52.6 USB registers 2321
52.6.1 USB control register (USB_CNTR) 2321
52.6.2 USB interrupt status register (USB_ISTR) 2324
52.6.3 USB frame number register (USB_FNR) 2328
52.6.4 USB Device address (USB_DADDR) 2328
52.6.5 USB LPM control and status register (USB_LPMCSR) 2329
52.6.6 USB battery charging detector (USB_BCDR) 2330
52.6.7 USB endpoint/channel n register (USB_CHEPnR) 2331
52.6.8 USB register map 2340
52.7 USBSRAM registers 2341
52.7.1 Channel/endpoint transmit buffer descriptor n (USB_CHEP_TXRXBD_n) 2342
52.7.2 Channel/endpoint receive buffer descriptor n [alternate] (USB_CHEP_TXRXBD_n) 2342

52.7.3 Channel/endpoint receive buffer descriptor n (USB_CHEP_RXTXBD_n) . . . 2344
52.7.4 Channel/endpoint transmit buffer descriptor n [alternate] (USB_CHEP_RXTXBD_n) . . . 2345
52.7.5 USBSRAM register map . . . 2346

53 Debug support (DBG) . . . 2347
53.1 Introduction . . . 2347
53.2 DBG functional description . . . 2348
53.2.1 DBG block diagram . . . 2348
53.2.2 DBG pins and internal signals . . . 2348
53.2.3 DBG reset and clocks . . . 2349
53.2.4 DBG power domains . . . 2349
53.2.5 Debug and low-power modes . . . 2349
53.2.6 Security . . . 2350
53.3 Serial-wire and JTAG debug port (SWJ-DP) . . . 2351
53.3.1 JTAG debug port . . . 2352
53.3.2 Serial-wire debug port . . . 2354
53.3.3 Debug port registers . . . 2355
53.3.4 Debug port register map . . . 2361
53.4 Access ports . . . 2362
53.4.1 Access port registers . . . 2362
53.4.2 Access port register map . . . 2367
53.5 ROM tables . . . 2368
53.5.1 MCU ROM table registers . . . 2368
53.5.2 MCU ROM table register map . . . 2372
53.5.3 Processor ROM table registers . . . 2373
53.5.4 Processor ROM table register map . . . 2376
53.6 Data watchpoint and trace unit (DWT) . . . 2378
53.6.1 DWT registers . . . 2378
53.6.2 DWT register map . . . 2390
53.7 Instrumentation trace macrocell (ITM) . . . 2393
53.7.1 ITM registers . . . 2393
53.7.2 ITM register map . . . 2400
53.8 Breakpoint unit (BPU) . . . 2401
53.8.1 BPU registers . . . 2401
53.8.2 BPU register map . . . 2406

53.9 Embedded Trace Macrocell (ETM) 2408
53.9.1 ETM registers 2408
53.9.2 ETM register map 2430
53.10 Trace port interface unit (TPIU) 2434
53.10.1 TPIU registers 2434
53.10.2 TPIU register map 2443
53.11 Cross-trigger interface (CTI) 2445
53.11.1 CTI registers 2445
53.11.2 CTI register map 2455
53.12 Microcontroller debug unit (DBGMCU) 2457
53.12.1 DBGMCU registers 2457
53.12.2 DBGMCU register map 2466
53.13 References 2468

54 Device electronic signature 2469
54.1 Unique device ID register (96 bits) 2469
54.2 Flash memory size data register 2470
54.3 Package data register 2471

55 Important security notice 2472

56 Revision history 2473

1 Documentation conventions

1.1 General information

The STM32U3 series devices have an Arm®(a) Cortex®-M33 core, with Arm® TrustZone®.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

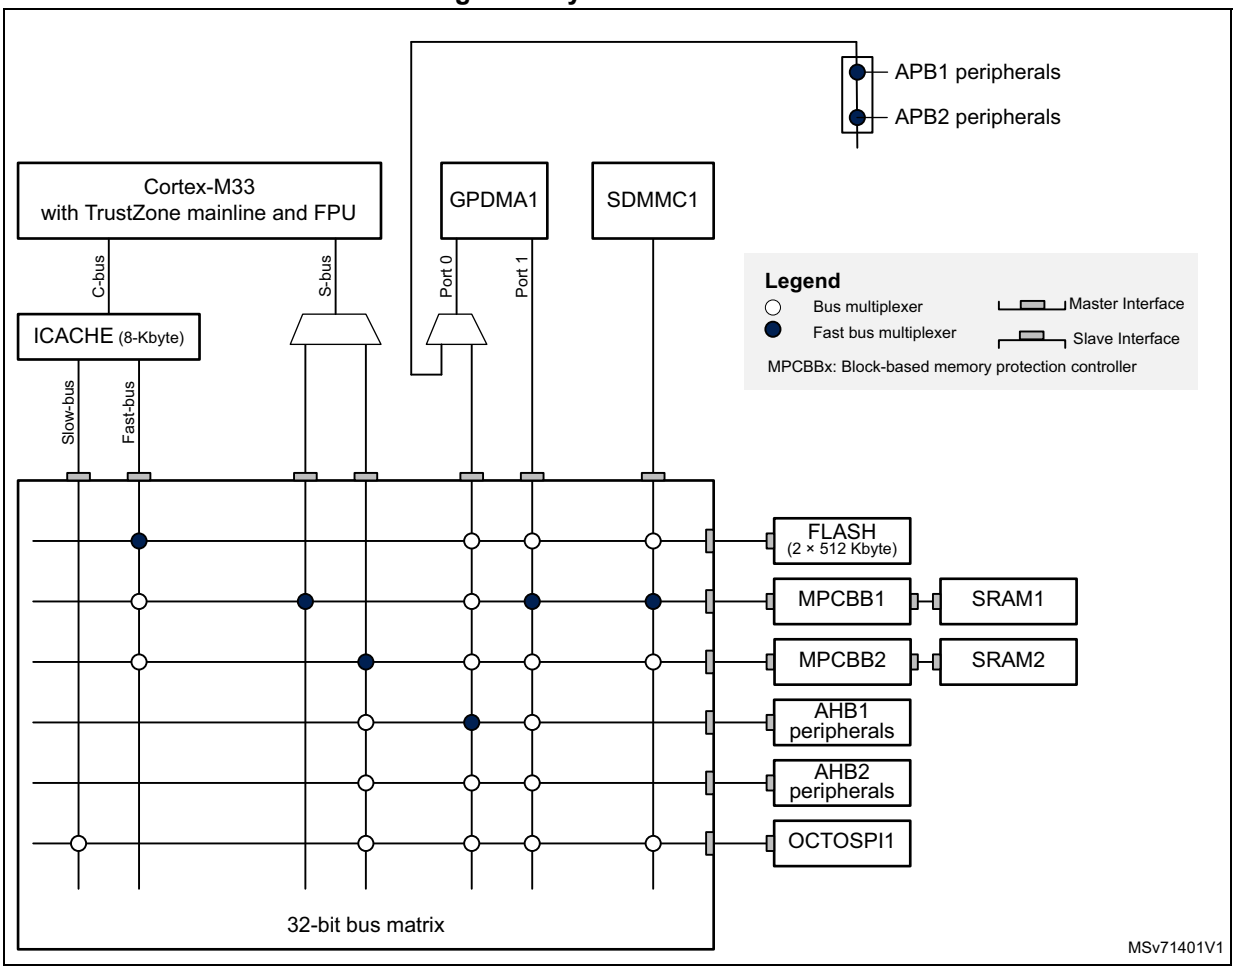
- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.

1.5 Availability of peripherals

For detailed availability of peripherals and their number across all sales types (depending on product line and package), refer to the device datasheet.

2 Memory and bus architecture

2.1 System architecture



The STM32U3 series architecture relies on an Arm Cortex-M33 core optimized for execution thanks to an instruction cache having a direct access to the embedded flash memory.

This architecture also features a 32-bit multilayer AHB bus matrix that interconnects:

- up to 7 masters:
  - Fast C-bus, connecting Cortex-M33 with Arm TrustZone mainline and FPU core to the internal SRAMs and flash memory through the instruction cache
  - Slow C-bus, connecting Cortex-M33 with Arm TrustZone mainline and FPU core to the OCTOSPI1 external memory through the instruction cache
  - Cortex-M33 with Arm TrustZone mainline and FPU core S-bus (two masters connected to two internal SRAMs without latency), and to peripherals and OCTOSPI1 external memory
  - GPDMA1 (general purpose DMA featuring two master ports)
  - SDMMC1
- up to 6 slaves:
  - internal flash memory (1 Mbytes)
  - internal SRAM1 (192 Kbytes)
  - internal SRAM2 (64 Kbytes)
  - AHB1 peripherals including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - OCTOSPI1

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

Figure 1. System architecture

2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the internal flash memory and to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in the code region. This bus targets the internal flash memory and the internal SRAMs (SRAM1 and SRAM2).

SRAM1 and SRAM2 are accessible on this bus with a continuous mapping.

2.1.2 Slow C-bus

This bus connects the C-bus of the Cortex-M33 core to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in the code region. This bus targets the external memories (OCTOSPI).

2.1.3 S-bus

This bus connects the system bus of the Cortex-M33 core to the bus matrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the internal SRAMs (SRAM1 and SRAM2), the AHB1 peripherals including the APB1 and APB2 peripherals, and the AHB2 peripherals.

SRAM1 and SRAM2 are accessible on this bus with a continuous mapping.

Note: The bus matrix has a zero latency when accessing SRAM1 and SRAM2*.*

2.1.4 GPDMA-bus

These buses connect the two AHB master interfaces of the GPDMA to the bus matrix. These buses target the internal flash memory, the internal SRAMs (SRAM1 and SRAM2), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals, the APB3 peripherals and the external memories through OCTOSPI.

2.1.5 SDMMC1 controller DMA bus

This bus connects the SDMMC1 DMA master interface to the bus matrix. This bus is used only by the SDMMC1 DMA to load/store data from/to the memory. This bus targets the data memories: internal flash memory, internal SRAMs (SRAM1 and SRAM2) and external memories through OCTOSPI.

2.1.6 Bus matrix

The bus matrix manages the access arbitration between masters. The arbitration uses a round-robin algorithm. This bus matrix features a fast bus multiplexer used to connect each master to a given slave without latency (see *Figure 1*). For the same master, other slaves undergo a latency of at least one cycle at each new access.

2.1.7 AHB/APB bridges

The three AHB/APB bridges provide full synchronous connections between the AHB and the APB buses, allowing flexible selection of the peripheral frequency.

Refer to Memory and bus architecture for the address mapping of the peripherals connected to these bridges.

After each device reset, all peripheral clocks are disabled (except for the internal SRAMs and flash memory interfaces). Before using a peripheral, its clock must be enabled in the RCC_AHBxENR and RCC_APBxENR registers.

Note: When an 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.2 Arm TrustZone security architecture

The security architecture is based on Arm TrustZone with the Armv8-M mainline extension.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

When the TrustZone is enabled, the SAU (security-attribution unit) and IDAU (implementation-defined-attribution unit) defines the access permissions based on secure and nonsecure states.

- SAU: Up to eight SAU configurable regions are available for security attribution.
- IDAU: provides a first memory partition as nonsecure or nonsecure callable attributes. The IDAU memory map partition is not configurable and fixed by hardware implementation (refer to *Figure 1* and to *Table 4* in *Section 2.3.2: Memory map and*

register boundary addresses). It is then combined with the results from the SAU security attribution and the higher security state is selected.

Based on IDAU security attribution, the flash memory, system SRAMs, and peripherals memory space are aliased twice for secure and nonsecure states. The external memories space is not aliased.

The table below shows an example of typical eight SAU regions mapping based on IDAU regions. The user can split and choose the secure, nonsecure or NSC regions for external memories as needed.

Table 1. Example of memory map security attribution versus SAU configuration regions

Region description	Address range	IDAU security attribution	SAU security attribution typical configuration	Final security attribution
Code - external memories	0x0000_0000 0x07FF_FFFF	Nonsecure	Secure, nonsecure or NSC(1)	Secure, nonsecure, or NSC
Code - flash memory and SRAM	0x0800_0000 0x0BFF_FFFF	Nonsecure	Nonsecure	Nonsecure
	0x0C00_0000 0x0FFF_FFFF	NSC	Secure or NSC	Secure or NSC
Code - external memories	0x1000_0000 0x17FF_FFFF	Nonsecure	Nonsecure	
	0x1800_0000 0x1FFF_FFFF			
SRAM	0x2000_0000 0x2FFF_FFFFF	Nonsecure		
	0x3000_0000 0x3FFF_FFFFF	NSC	Secure or NSC	Secure or NSC
Peripherals	0x4000_0000 0x4FFF_FFFFF	Nonsecure	Nonsecure	Nonsecure
	0x5000_0000 0x5FFF_FFFFF	NSC	Secure or NSC	Secure or NSC
External memories	0x6000_0000 0xDFFF_FFFF	Nonsecure	Secure, nonsecure or NSC	Secure, nonsecure or NSC

1. NSC = nonsecure callable

2.2.1 Default Arm TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is detailed below:

- CPU:
  - Cortex-M33 is in secure state after reset. The boot address must be at a secure address.
- Memory map:
  - SAU is fully secure after reset. Consequently, all memory map is fully secure. Up to height SAU configurable regions are available for security attribution.
- Flash memory:
  - The flash memory security area is defined by watermark user options.
  - Flash block-based security attributions are nonsecure after reset.
- SRAMs:
  - All SRAMs are secure after reset. MPCBBx (block-based memory protection controller) are secure.

- External memories:
  - OCTOSPI does not support any TrustZone protection.
- Peripherals (see *Table 2* and *Table 3* for a list of securable and TrustZone-aware peripherals)
  - Securable peripherals are nonsecure after reset.
  - TrustZone-aware peripherals are nonsecure after reset. Their secure configuration registers are secure.
- All GPIOs secure after reset
- Interrupts:
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and nonsecure state.
  - TZIC: All illegal access interrupts are disabled after reset (see *Section 2.2: Arm TrustZone security architecture*).

2.2.2 Arm TrustZone peripheral classification

When the TrustZone security is active, a peripheral can be either securable or TrustZone-aware type as follows:

- Securable: peripheral protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties
- TrustZone-aware: peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure.

Refer to *Section 2.2: Arm TrustZone security architecture* for more details.

The tables below list the securable and TrustZone-aware peripherals within the system.

Table 2. Securable peripherals by TZSC

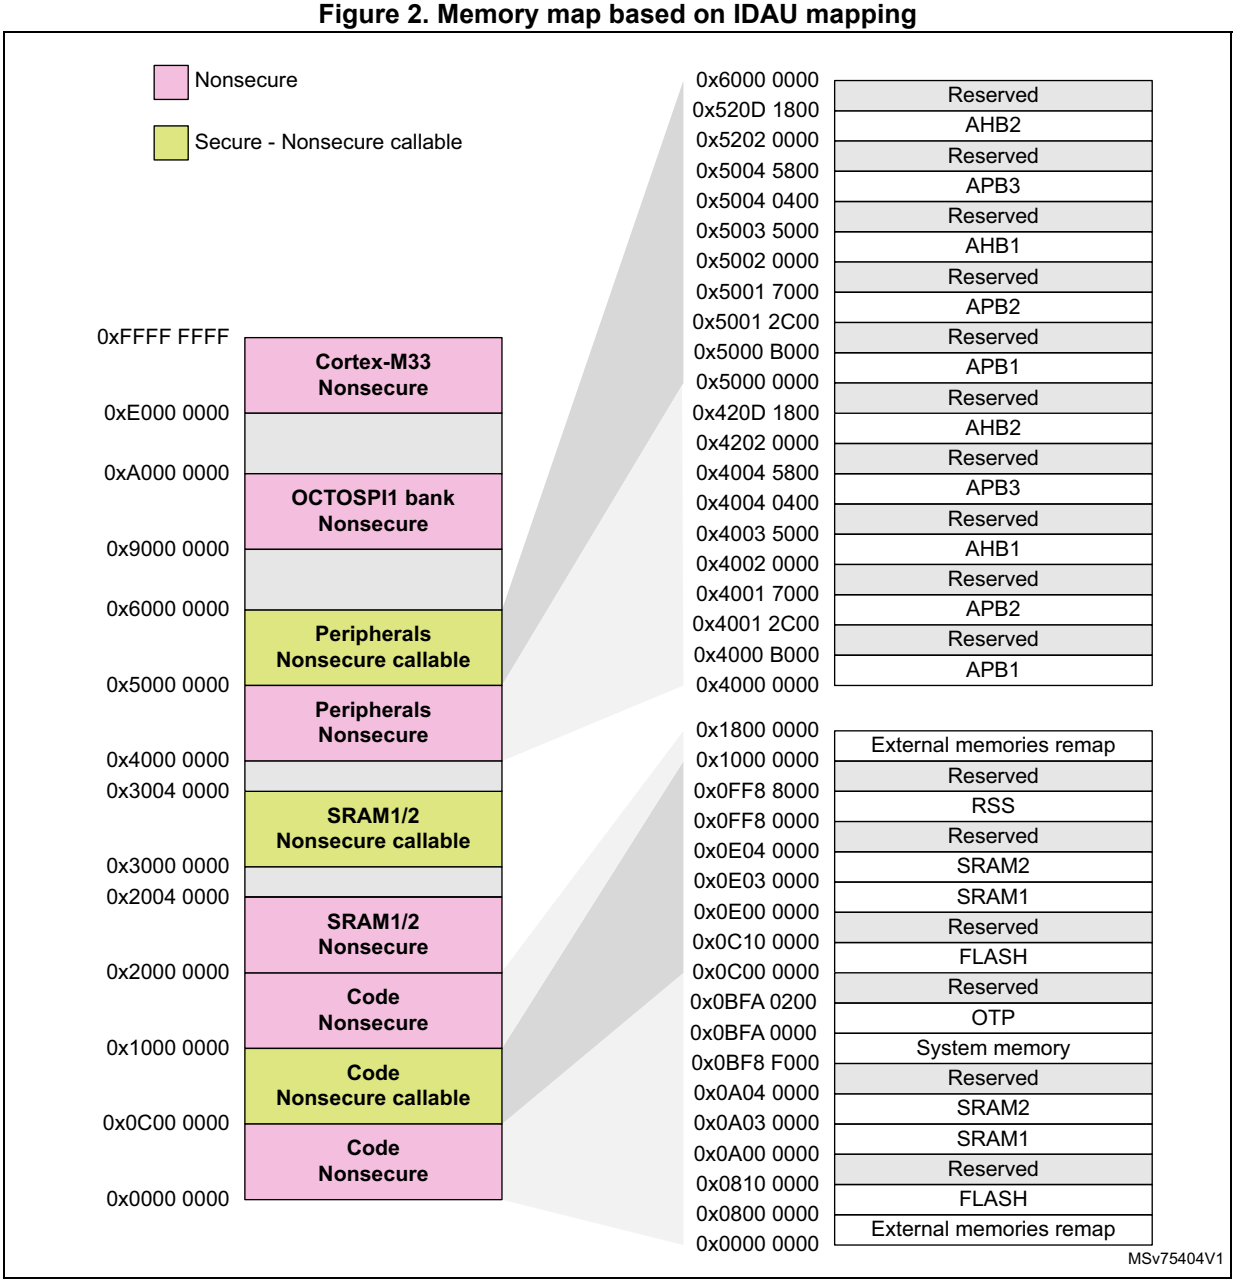
2.3 Memory organization



2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Figure 2. Memory map based on IDAU mapping

All memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. The following table gives the boundary addresses of the peripherals available in the devices.

Table 4. Memory map and peripheral register boundary addresses

Bus	Secure boundary address	Nonsecure boundary address	Size (bytes)	Peripheral	Peripheral register map section number
AHB2	0x520D 1800 - 0x5FFF FFFF	0x420D 1800 - 0x4FFF FFFF	223 M	Reserved	-
	0x520D 1400 - 0x520D 17FF	0x420D 1400 - 0x420D 17FF	1 K	OCTOSPI1	*19.7.28*

2.3.3 Embedded SRAMs

The devices feature up to 256-Kbyte SRAMs:

- 192-Kbyte SRAM1
- 64-Kbyte SRAM2

These SRAMs can be accessed as bytes, half-words (16 bits), or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1 and SRAM2 through the system bus or through the C-bus depending on the selected address.

When the TrustZone security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as nonsecure with a block granularity. For more details, refer to *Section 5: Global TrustZone controller (GTZC)*.

SRAM features are detailed in *Section 6.3.1: Internal SRAMs features*.

2.3.4 Flash memory overview

The flash memory is composed of two distinct physical areas:

- the main flash memory block, that contains the application program and user data
- the information block, that is composed of the following parts:
  - option bytes for hardware and memory protection user configuration
  - system memory that contains ST proprietary code
  - OTP (one-time programmable) area

The flash memory interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the flash memory operations (program/erase) controlled through the flash memory registers plus security access control features. Refer to *Section 7: Embedded flash memory (FLASH)* for more details.

3 System security

The STM32U3 series devices are designed with a comprehensive set of security features, some of which being based on the standard Arm TrustZone technology.

These security features simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEM and third-party developers, by facilitating the reuse, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on STM32U3 series devices.

3.1 Key security features

- Resource isolation using privilege mode and Armv8-M mainline security extension of the Cortex-M33, extended to securable I/Os, memories, and peripherals
- Secure firmware installation (SFI) with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the download of the image through USART, USB, I2C, I3C, SPI, FDCAN, and JTAG
- Secure boot thanks to the unique boot entry feature and hide-protect area (HDP) mechanism
- Secure storage, featuring:
  - Nonvolatile on-chip secure storage, protected with secure and HDP areas
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID and JTAG 32-bit device-specific ID
  - On-chip enhance storage technology, using hardware secret nonvolatile derived hardware unique keys (DHUK), and application-defined volatile boot hardware key (BHK), both loadable by hardware to the DPA-resistant SAES engine
- General purpose cryptographic acceleration:
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM, and CCM chaining modes
  - Secure AES 256-bit security coprocessor, supporting ECB, CBC, CTR, GCM and CCM chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting SHA-1 checksums and SHA-2 secure hash
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified
  - Coupling and chaining bridge (CCB) for special coupling and chaining operations (involving PKA, SAES, RNG peripherals) to protect private keys used in PKA protected operations.
- Flexible life-cycle scheme with readout protection (RDP), including support for product decommissioning (auto-erase)
  - Debug protection, depending on the RDP level
  - Optional password-based RDP level regressions, including for RDP level 2
- Protected firmware distribution scheme, using TrustZone and RDP level 0.5

- External tamper detection and protection against frequency attacks
  - Five passive inputs, available in all power modes

3.2 Secure install

The secure firmware install (SFI) is an STMicroelectronics secure service authenticated and decrypted by the immutable RSS code stored in the device. The SFI allows secure and counted installation of OEM firmware in the untrusted production environment (such as the OEM contract manufacturer).

The confidentiality of the installed images written in the internal flash memory, is also protected, using the AES.

The SFI native service leverages the following hardware security features:

- secure boot (see *Section 3.3*)
- resource isolation using TrustZone (see *Section 3.5*)
- temporal isolation using hide protection (see *Section 3.6.1*)
- secure execution (see *Section 3.7*)
- secure storage, with associated cryptographic engines (see *Section 3.8* and *Section 3.9*)

Further information can be found in the application note: *Overview secure firmware install (SFI) (*AN4992).

3.3 Secure boot

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The actual functions of the secure boot depend on the availability of TrustZone features, and on the firmware stored in the device. However, the secure boot typically initializes the secure storage.

The device trusted firmware-M (TFM) application, supported by the STM32 ecosystem, provides a root of trust solution including secure boot functions. For more information, refer to the user manual *Getting started with STM32CubeU5 TFM application* (UM2851).

In the devices, the secure boot takes benefit of hardware security features such as:

- resource isolation using TrustZone (see *Section 3.5*)
- temporal isolation using hide protection (see *Section 3.6.1*)
- secure execution (see *Section 3.7*)
- secure install and update (see *Section 3.2* and *Section 3.4*)
- secure storage, with associated cryptographic engines if available (see *Section 3.8* and *Section 3.9*)

This section describes the features specifically designed for secure boot.

3.3.1 Unique boot entry and BOOT_LOCK

When TrustZone is activated (TZEN = 1) and the BOOT_LOCK secure option bit is cleared, the application selects a boot entry point located either in the system flash memory (see the next section), or in the secure user flash memory, at the address defined by option bytes of FLASH_SBOOT0R.

When TrustZone is activated (TZEN = 1) and the BOOT_LOCK secure option bit is set, the device unique boot entry is the unmodifiable secure address defined by of FLASH_SBOOT0R option bytes. All these option bytes cannot be modified by the application anymore when BOOT_LOCK is set.

Note: As long as it is cleared, the BOOT_LOCK option bit can be set without any constraint. But once set, the BOOT_LOCK option bit cannot be cleared when RDP level > 0.

For more information on the boot mechanisms, refer to *Section 4: Boot modes*.

3.3.2 Immutable root of trust in system flash memory

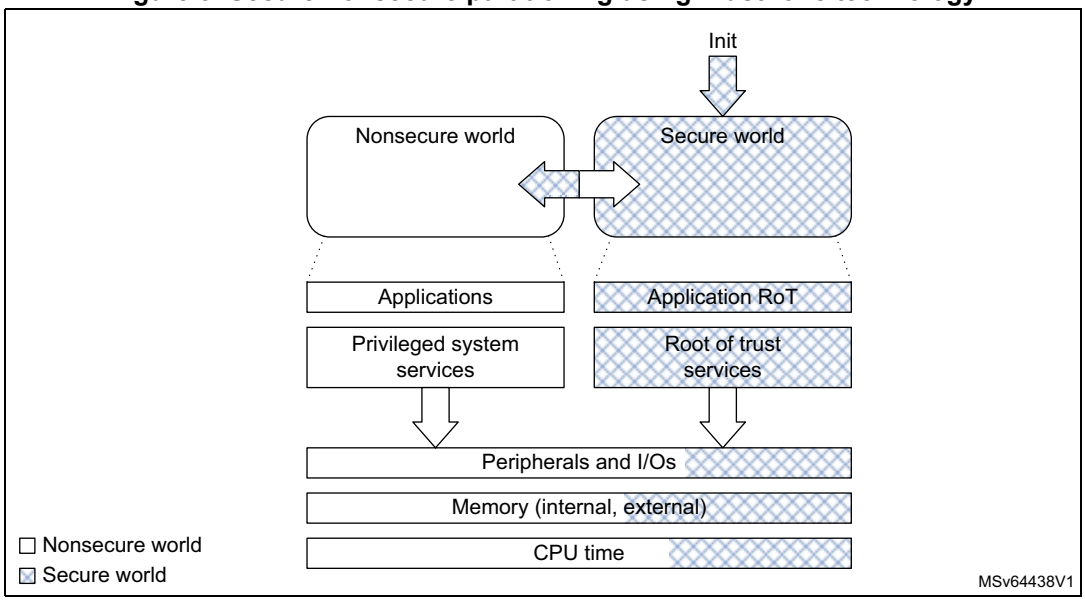
The immutable root-of-trust code stored in the system flash memory is first used to initiate SFI, allowing secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when a secure application sets the SYSCGFG_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when the BOOT_LOCK secure option bit is set, and the secure address defined by option bytes of FLASH_SBOOT0R are set on the secure user flash memory.

3.4 Secure update

The secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on the availability of the TrustZone features, and on the firmware stored in the device.

The device trusted firmware-M (TFM) application, supported by the STM32 ecosystem, allows the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.



A firmware update can be done either on a single firmware image including both secure and nonsecure parts, or on the secure (respectively nonsecure) part of the firmware image, independently.

In the devices, the secure update application leverages the same hardware security as the firmware install described in *Section 3.2*. For more information, refer to the user manual: *Getting started with STM32CubeU5 TFM application* (UM2851).

3.5 Resource isolation using TrustZone

In the STM32U3 series devices, the hardware and software resources can be partitioned so that they exist either in the secure world or in the nonsecure world, as shown in the figure below.

Figure 3. Secure/nonsecure partitioning using TrustZone technology

Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after the reset of the device.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the nonsecure world.

Note: The secure code is typically small and rarely modified, while nonsecure code is more exposed, and prone to firmware updates.

3.5.1 TrustZone security architecture

The Armv8-M TrustZone technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. The device TrustZone hardware features include:

- the Armv8-M mainline security extension of Cortex-M33, enabling a new processor secure state, with its associated secure interrupts
- the dynamic allocation of memory and peripherals to TrustZone using eight security attribution unit (SAU) regions of Cortex-M33
- a global TrustZone framework (GTZC), extending the TrustZone protection against transactions coming from other masters in the system than the Cortex-M33
- TrustZone-aware embedded flash memory and peripherals

Note: The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

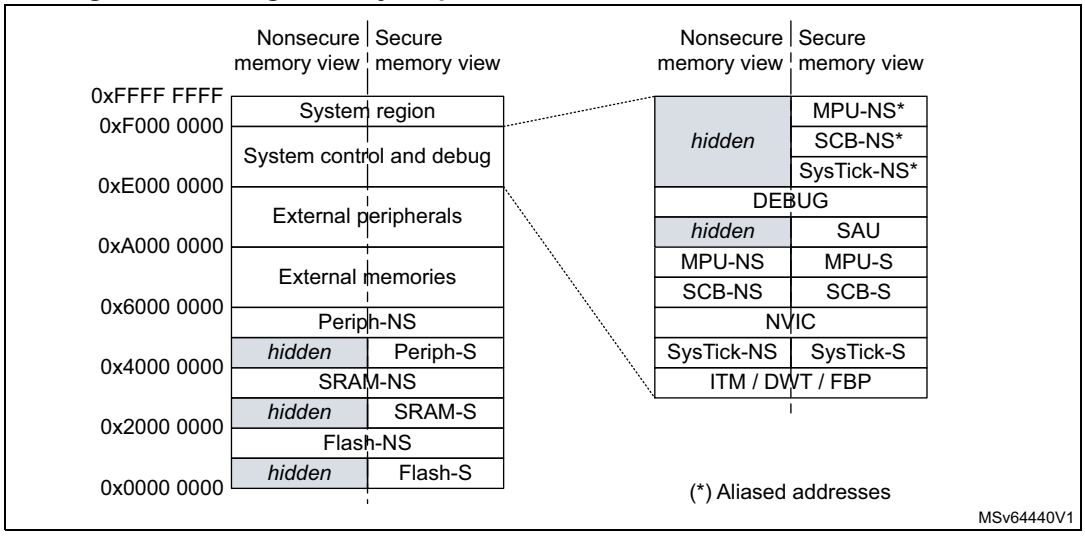
3.5.2 Armv8-M security extension of Cortex-M33

The Arm security extension of the Cortex-M33 is an evolution, not a revolution. It uses the programmer model from earlier Cortex-M subfamilies like Cortex-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU. Armv8-M also uses the nested vectored interrupt controller (NVIC).

The Armv8-M TrustZone implementation in STM32U3 series devices is composed of the following features:

- a new processor state, with almost no additional code/cycle overhead, as opposed to Armv8-A TrustZone that uses a dedicated exception routine for triggering a secure/nonsecure world change
- two memory map views of a shared 4-Gbyte address space
- a low interrupt latency for both secure and nonsecure domains, and a new interrupt configuration for security grouping and priority setting
- separated exception vector tables for the secure and nonsecure exceptions
- micro-coded context preservation
- banking of specific registers across secure/nonsecure states, including stack pointers with stack-limit checkers
- banking of the following Cortex-M33 programmable components (two separate units for secure and nonsecure):
  - SysTick timer
  - MPU configuration registers (twelve MPU regions in secure, eight in nonsecure)
  - some of the system control block (SCB) registers
- new system exception (SecureFault) for handling of security violations
- configurable debug support, as defined in *Section 3.11*

For more information, refer to *STM32 Cortex-M33 MCUs programming manual* (PM0264).



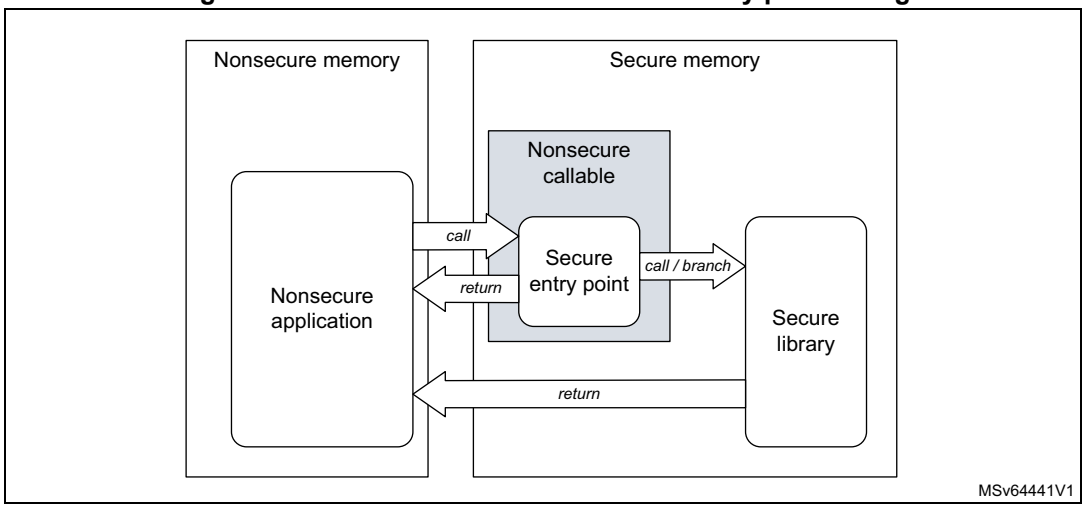
3.5.3 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated on *Figure 4*, the Armv8-M nonsecure memory view is similar to Armv7-M (that can be found in Cortex-M4), with the difference that the secure memory is hidden. The secure memory view shows the flash memory, SRAM, and peripherals that are only accessible while the Cortex processor executes in Secure state.

Figure 4 shows the 32-bit address space viewed after the SAU configuration by the secure code.

Figure 4. Sharing memory map between CPU in secure and nonsecure state



The Cortex processor state (and associated rights) depends on the security attribute assigned to the memory region where it is executed:

- A processor in a nonsecure state only executes from nonsecure (NS) program memory, while a processor in a secure state only executes from secure (S) program memory.
- While running in the secure state, the processor can access data from both S and NS memories. Running in the nonsecure state, the CPU is limited to nonsecure memories.

In order to manage transitions to the secure world, developers must create nonsecure callable (NSC) regions that contain valid entry points to the secure libraries. The first instruction in these entry points must be the new secure gate (SG) instruction, used by the nonsecure code to call a secure function (see *Figure 5*).

Figure 5. Secure world transition and memory partitioning

Programming security attributes

In Cortex-M33, the static implementation defined attribution unit (IDAU) works in conjunction with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS, or NSC) to a specific address, as shown in the table below.

Table 5. Configuring security attributes with IDAU and SAU

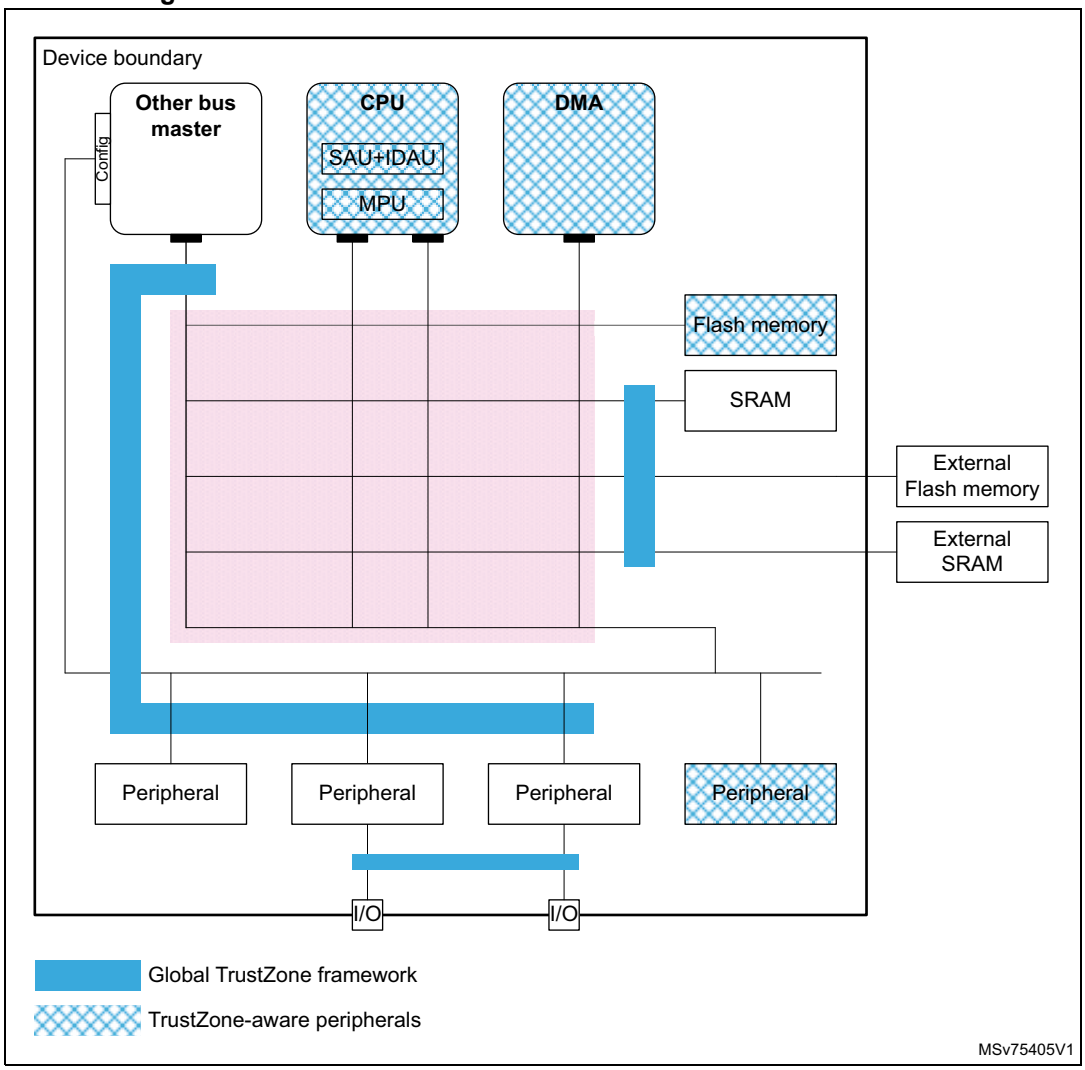
IDAU security attribution	SAU security attribution(1)	Final security attribution
Nonsecure	Secure	Secure
	Secure-NSC	Secure-NSC
	Nonsecure	Nonsecure
Secure-NSC	Secure	Secure
	Nonsecure	Secure-NSC

1. Defined regions are aligned to 32-byte boundaries.

The SAU can only be configured by the Cortex-M33 in the secure-privilege state. When the TrustZone is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program the SAU to create NSC or NS regions, as shown in *Table 5*.

Note: The SAU/IDAU settings are applicable only to the Cortex-M33*. The other masters like DMA are not affected by these policies.*

A memory space not covered by an SAU region is fixed as secure.



For more information on memory security attribution using IDAU/SAU, refer to the application note *Arm TrustZone features for STM32L5, STM32U3, and STM32U5 series* (AN5347).

3.5.4 Memory and peripheral allocation using GTZC

Global TrustZone framework architecture

On top of the Armv8-M TrustZone security extension in Cortex-M33, the devices embed complementary security features that reinforce, in a flexible way, the isolation between the secure and the nonsecure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy memories and peripherals against nonsecure transactions coming from other masters than the Cortex-M33.

Figure 6. Global TrustZone framework and TrustZone awareness

Securing peripherals

When the TrustZone security is active, a peripheral is either securable through the TZSC in GTZC, or is natively TrustZone-aware, as shown in *Figure 6*:

- A securable peripheral or memory is protected by an AHB/APB firewall gate, that is controlled by the TrustZone security controller (TZSC).
- A TrustZone-aware peripheral or memory is connected directly to the AHB or APB interconnect, implementing a specific TrustZone behavior, such as a subset of secure registers, or a secure memory area.

When a securable peripheral is made secure-only with the GTZC, if this peripheral is master on the interconnect (such as SDMMC), it automatically issues secure transactions. The SDMMC is an example of securable master. TrustZone-aware AHB masters like Cortex-M33 or DMAs, drive a secure signal in the AHB interconnect, according to their security mode, independently to the GTZC.

Note: Like with TrustZone, a peripheral can be made privileged-only with TZSC (see Section 3.6.2). In this case, if this peripheral is master on the interconnect, it automatically issues privileged transactions.

Securing memories with TZSC and MPCBB

The MPCBB resources in GTZC provide the capability to configure the security and privilege of embedded SRAM blocks, as defined in the following table.

Table 6. MPCBBx resources

Memory	MPC resource	Type of filtering	Memory size (Kbytes)	Block size (Bytes)	Number of super-blocks	Default security
SRAM1	GTZC1_MPCBB1	Block based, managing security and privilege	192	512(1)	12	Secure privileged(2)
SRAM2	GTZC1_MPCBB2		64		4	

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, nonsecure unprivileged otherwise.

Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:

- statically programmed during the secure boot, locked and not changed afterwards
- dynamically reprogrammed using a specific application code or real-time kernel

When the dynamic option is selected and the configuration is not locked:

- MPCBB secure blocks size can be changed by a secure software. This software can be unprivileged if the particular block is not privileged-only.
- The secure (respectively privilege) state of each peripheral can be changed writing to GTZC_TZSC_SECCFRGx (respectively GTZC_TZSC_PRIVCFGRx) registers.

Securing peripherals with TZSC

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals. The list of these peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

When the TrustZone is activated, peripherals are set as nonsecure and unprivileged after reset.

Note: When the TrustZone is deactivated, the resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only (see Section 3.6.2).

-

TrustZone-aware peripherals

The devices include the following TrustZone-aware peripherals:

- GPIOA to GPIOH
- GTZCx_MPCBB, GTZCx_TZIC and GTZCx_TZSC (GTZC blocks)
- EXTI
- Flash memory
- RCC and PWR
- GPDMA
- SYSCFG registers
- RTC and TAMP
- MCU debug unit DBGMCU

The way illegal accesses to these peripherals are monitored through the TZIC registers is described in *Section 5: Global TrustZone controller (GTZC)*.

For more details, refer to *Section 3.5.5*.

TrustZone illegal access controller (TZIC)

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone-aware peripherals, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone enabled (TZEN = 1). All accesses to TZIC registers must be secured and privileged.

For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

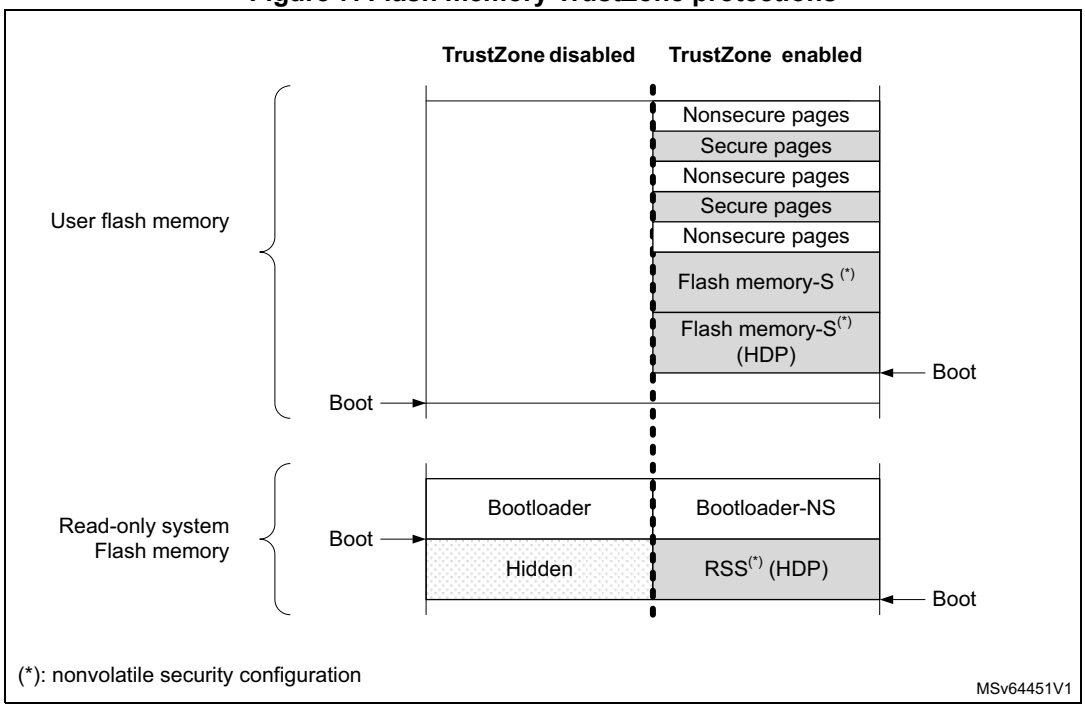
Note: By default, all events are masked.

3.5.5 Managing security in TrustZone-aware peripherals

This section gives more details on how the security is implemented in the TrustZone-aware peripherals listed in the previous section.

Embedded flash memory

When the TrustZone security is enabled through option bytes (TZEN = 1), the whole flash memory is secure after reset and the following protections, shown in *Figure 7*, are available to the application:



- nonvolatile user secure areas, defined with nonvolatile secure user option bytes
  - watermark-based secure only area (x2)
  - secure hide protection (HDP) area, stickily hidden after boot (x2)
- volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as nonsecure (example: outside the watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers.

Note: All areas are aligned on the flash memory page granularity.

The flash memory area can be configured as secure while it is tagged as nonsecure in Cortex-M33 IDAU/SAU. In this case, nonsecure accesses by the CPU to the flash memory are denied.

Erase or program operations can be available to secure (resp. nonsecure) code only for secure (resp. nonsecure) pages or memory. A flash memory is considered secure if at least one page is secure.

Figure 7. Flash memory TrustZone protections

As shown in *Section 7: Embedded flash memory (FLASH)*, when TrustZone is activated (TZEN = 1), the application code can use the HDP area that is part of the flash memory watermark-based secure area. Indeed, when the application modifies the HDPx_ACCDIS byte to a value different than the reset value, data read, write, and instruction fetch on this HDP area are denied until the next system reset.

For example, the software code in the secure flash memory HDP area can be executed only once, with any further access to this area denied until the next system reset. Additionally, any flash memory page belonging to an active HDP area cannot be erased anymore.

When the TrustZone is deactivated (TZEN = 0), the volatile/non-volatile secure area features are deactivated and all secure registers are RAZ/WI.

See *Section 7: Embedded flash memory (FLASH)* for more details.

Direct memory access controllers (GPDMA)

When a DMA channel x is defined as secure (SECx = 1 in GPDMA_SECCFGR), the source and destination transfers can be independently set as secure or nonsecure by a secure application using SSEC and DSEC bits in GPDMA_CxTR1.

The table below summarizes these security options available in each DMA channel.

Table 7. DMA channel use (security)(1)

Destination type	Secure DMA channel x (SECx = 1)		Nonsecure DMA channel y (SECy = 0)	
	Secure source	Nonsecure source	Secure source	Nonsecure source
Secure destination	OK	OK(2)	Transfer blocked	
Nonsecure destination	OK(3)	OK(4)	Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros. Also an illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.
2. If the source is a memory, the transfer is only possible if SSEC = 0, otherwise the transfer is blocked.
3. If the destination is a memory, the transfer is only possible if DSEC = 0, otherwise the transfer is blocked.
4. If the transfer is memory-to-memory, the transfer is only possible if SSEC = 0 and DSEC = 0, otherwise the transfer is blocked.

When a channel is configured as secure:

- Registers allocated to this channel (excluding GPDMA_SECCFGR, GPDMA_PRIVCFGR, and GPDMA_RCFGLOCKR) are read as zero. Write are ignored for nonsecure accesses. A secure illegal access event may also be triggered toward the TZIC peripheral.
  - Writes to GPDMA_SECCFGR and GPDMA_RCFGLOCKR must be secure. For each bit in GPDMA_PRIVCFGR, write must be secure if the corresponding bit in GPDMA_SECCFGR is set.
- In linked-list mode, the loading of the next linked-list data structure from memory is performed with secure transfers.
- When switching to a nonsecure state, the secure application must abort the channel or wait until the secure channel is completed before doing the switch.

Note: DMA secure channels are not available when TrustZone is deactivated.

When a channel is configured as nonsecure, in linked-list mode, the loading of the next linked-list data structure from memory is performed with nonsecure transfers.

See *Section 15: General purpose direct memory access controller (GPDMA)* for more details.

Power control (PWR)

When the TrustZone security is activated (TZEN = 1), the selected PWR registers can be secured through PWR_SECCFGR, protecting the following PWR features:

- low-power mode setup
- wake-up (WKUP) pins definition
- voltage detection and monitoring
- backup domain control

Other PWR configuration bits become secure:

- when the system clock selection is secure in the RCC: the voltage scaling (VOS) and the regulator booster (BOOSTEN) configurations become secure.
- when a GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.

See *Section 9: Power control (PWR)* for details.

Secure clock and reset (RCC)

When the TrustZone security is activated (TZEN = 1) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets become TrustZone-aware:

- If the peripheral is securable and programmed as secure in the TZSC, the peripheral clock and reset bits become secure.
- If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure as soon as at least one function is configured as secure inside the peripheral.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

Additionally, the following configurations can be made secure-only using RCC_SECCFGR:

- External clock (such as HSE or LSE), internal oscillator (such as HSI, MSI, or LSI)
- AHB prescaler
- System clock source selection
- Reset flag clearing
- Automatic internal oscillator waking up configuration

See *Section 10: Reset and clock control (RCC)* for details.

Real time clock (RTC)

Like all TrustZone-aware peripherals, a nonsecure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC.

After a backup domain power-on reset, all RTC registers can be read or written in both secure and nonsecure modes. The secure boot code can then change this security setup, making registers alarm A, alarm B, wake-up timer, and timestamp secure or not, using RTC_SECCFGR.

When the SEC bit is set in secure-only RTC_SECCFGR:

- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR is always possible in secure and nonsecure modes. All the other RTC registers can be read only in secure mode.

When the SEC is cleared in secure-only RTC_SECCFGR, it is still possible to restrict access in secure mode to some RTC registers by setting dedicated control bits: INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC, and ALRBSEC.

Note: The RTC security configuration is not affected by a system reset.

See *Section 43: Real-time clock (RTC)* for more details.

Tamper and backup registers (TAMP)

Like all TrustZone-aware peripherals, a nonsecure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC.

After a backup domain power-on reset, all TAMP registers can be read or written in both secure and nonsecure modes. The secure boot code can change this security setup, making some registers secure or not as needed, using the TAMP_SECCFGR register.

When TAMPSEC is set in TAMP_SECCFGR:

- Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
- Reading the TAMP registers (except for TAMP_SECCFGR, TAMP_PRIVCFGR and TAMP_MISR) returns zero if the access is nonsecure. Backup registers have their own read protection (see below).

The application can also:

- make TAMP_COUNTR register read and write secure-only by setting the CNT1SEC bit in TAMP_SECCFGR secure register
- in backup registers increase security for two of the three protection zones configured using BKPRWSEC[7:0] and BKPWSEC[7:0] bitfields in TAMP_SECCFGR:
  - protection zone 1 is read nonsecure, write nonsecure
  - protection zone 2 is read nonsecure, write secure
  - protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See *Section 44: Tamper and backup registers (TAMP)* for more details.

General-purpose I/Os (GPIO)

When the TrustZone security is activated (TZEN = 1), each I/O pin of the GPIO port can be individually configured as secure through the GPIOx_SECCFGR registers. Only a secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin of GPIO is set as secure.

When an I/O pin is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE), and I/O data are RAZ/WI in case of nonsecure access.

When the digital alternate function is used (input/output mode), in order to protect the data transiting from/to the I/O managed by a secure peripheral, the devices add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- If the peripheral is secure, the I/O pin must also be secure to allow input/output of data.
- If the peripheral is not secure, the connection is allowed regardless of the I/O pin state.

The TrustZone-aware logic around GPIO ports, used as the alternate function, is summarized in the table below.

Table 8. Secure alternate function between peripherals and allocated I/Os

Security configuration		Alternate function logic		Comment
Peripheral	**Allocated I/O pin**	**Input**	**Output**	
Secure	Secure	I/O data	Peripheral data	-
Nonsecure				Out of reset configuration
Secure	Nonsecure	Zero	Zero	-
Nonsecure		I/O data	Peripheral data	

The following table lists peripherals which, when nonsecure, cannot be connected to secure I/Os configured for an analog function with analog switch, thanks to hardware that blocks such connections.

Table 9. Nonsecure peripherals not connectable to secure I/Os

Peripheral	Analog function(1)	Input	Output	How to set a peripheral or function as secure
ADC1	ADC1_INy	X	-	Set ADC12SEC in GTZC1_TZSC_SECCFGR3
ADC2	ADC2_INy			
OPAMPx	OPAMPx_VINM, OPAMPx_VINP			Set OPAMPSEC in GTZC1_TZSC_SECCFGR1
COMPx	COMPx_INPy, COMPx_INMy			Set COMPSEC in GTZC1_TZSC_SECCFGR2

1. Used to find the I/O corresponding to the signal/function on the package (refer to the product datasheet).

Finally, regarding GPIO and security, *Table 10* below summarizes the list of peripheral functions that do not have any hardware protection linked to TrustZone. The listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral function is nonsecure.

For example, when a secure application sets PA4 as secure to be used as LPTIM2_OUT, if the DAC is nonsecure, it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is nonsecure, it can be programmed to capture the USART input traffic through the TAMP_IN function.

It is important that, for each case described in *Table 10*, the secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential), then the secure application must configure the TAMP as secure even if it is not used by the secure application.

Note: How to make a peripheral secure is summarized in the right column of Table 10.

Table 10. Nonsecure peripherals connectable to secure I/Os

Peripheral	Signal(1)	Input	Output	How to set the peripheral or function as secure
DAC	DAC1_OUTx	-	X	Set DAC1SEC in GTZC1_TZSC_SECCFGR3.
OPAMP	OPAMPx_VOUT	-	X	Set OPAMPSEC in GTZC1_TZSC_SECCFGR1
USB	USB_VBUS	X	X	Set USBSEC in GTZC1_TZSC_SECCFGR2
TAMP	TAMP_INx	X	-	Set TAMPSEC in TAMP_SECCFGR

Table 10. Nonsecure peripherals connectable to secure I/Os (continued)

Peripheral	Signal[1]	Input	Output	How to set the peripheral or function as secure
RTC	RTC_OUTx	-	X	Set SEC in RTC_SECCFGR.
	RTC_TS	X	-	Set TSSEC in RTC_SECCFGR.
PWR	WKUPx	X	-	Set WUPxSEC in PWR_SECCFGR.
RCC	LSCO	-	X	Set LSESEC in RCC_SECCFGR.
EXTI	EXTIx	X	-	Set SECx bit in EXTI_SECCFGR.

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to *Section 12: General-purpose I/Os (GPIO)* for more details.

Extended interrupts and event controller (EXTI)

When the TrustZone security is activated (TZEN = 1), the EXTI is able to protect event register bits from being modified by nonsecure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGR1. When an input event is configured as secure, only a secure application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

The security configuration in EXTI_SECCFGR1 can be globally locked after reset in EXTI_LOCKR.

See *Section 17: Extended interrupts and event controller (EXTI)* for more details.

System configuration controller (SYSCFG)

Like all TrustZone-aware peripherals, when the TrustZone security is activated (TZEN = 1), a nonsecure read/write access to a secured SYSCFG register is RAZ/WI. Such access also generates an illegal access event that triggers a secure illegal access interrupt if the SYSCFG illegal access event is not masked in the TZIC.

See *Section 13: System configuration controller (SYSCFG)* for more details.

Microcontroller debug unit (DBGMCU)

The MCU debug component (DBGMCU) helps the debugger, providing support for:

- low-power mode behavior during debug
- peripheral freeze during debug, applicable to I2Cs, IWDG, WWDG, timers, low-power timers, and GPDMA channels

The DBGCMU is a TrustZone-aware peripheral, managing accesses to its control registers as described in *Table 11*.

Table 11. TrustZone-aware DBGMCU access management

Debug profile	Peripheral status(1)	DBG_xx_STOP control bits	
		Write access	Read access
Nonsecure invasive (SPIDEN = 0)	NS	Yes (S(2) or NS)	Yes (S or NS)
	S	None (S or NS)	
Secure invasive (SPIDEN = 1)	NS	Yes (S or NS)	
	S	Yes (S only)	

1. As reported by the GTZC, the TrustZone-aware peripheral or the DMA channel.
2. Secure access from the debugger is converted to nonsecure access in the device.

Refer to *Section 53: Debug support (DBG)* for more details.

3.5.6 Activating TrustZone security

The TrustZone is deactivated by default in all STM32U3 series devices. It can be activated by setting the TZEN user option bit in FLASH_OPTR when in RDP level 0. Once TZEN has changed from 0 to 1, the default security state, after reset, is always the following:

- CPU subsystem
  - Cortex-M33 exits reset in secure state, hence the boot address must point toward a secure memory area.
  - All interrupt sources are secure (in NVIC).
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure.
- Embedded flash memory
  - Flash memory nonvolatile secure areas (with their HDP zone), are defined with nonvolatile registers FLASH_SECWMxR (x = 1, 2). Default secure option bytes setup is all user flash secure, without HDP area defined.
  - Volatile block-based security attributions of the flash memory are nonsecure. The secure boot code can change this setup, making the blocks secure.
- Embedded SRAM memories
  - All SRAMs are secure, as defined in GTZC/MPCBB (see *Section 3.5.4*). The secure boot code can change this security setup, making the blocks secure or not.
- External memories are nonsecure
- All GPIOs are secure.
- All GPDMA channels are nonsecure.
- Backup registers are nonsecure.
- Peripherals and GTZC:
  - Securable peripherals are nonsecure and unprivileged.
  - TrustZone-aware peripherals are nonsecure, with their secure configuration registers being secure.
  - All illegal access interrupts in GTZC/TZIC are disabled.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

3.5.7 Deactivating TrustZone security

Once TrustZone is activated, it can only be deactivated during an RDP regression to level 0.

Note: Such RDP regression triggers the erase of embedded memories (SRAM1, SRAM2, flash memory), and the reset of all peripherals, including all cryptographic engines.

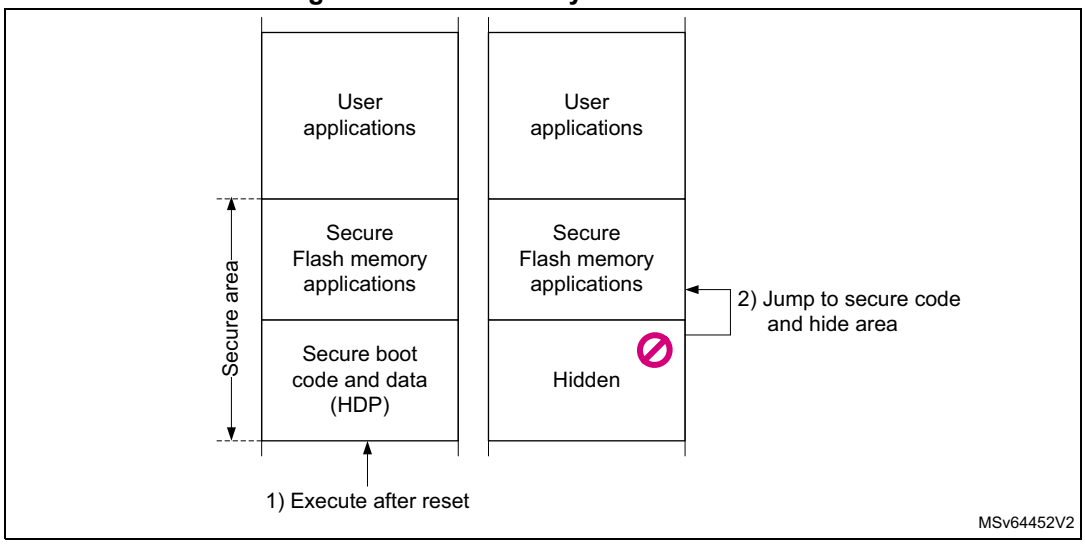
After the TrustZone deactivation, most of the features mentioned in *Section 3.5* are no longer available:

- The nonvolatile secure area of the embedded flash memory is deactivated, including the HDP area.
- The NVIC only manages nonsecure interrupts.
- All secure registers in TrustZone-aware peripherals are RAZ/WI.

Note: When the TrustZone is deactivated, the resource isolation using privilege stays available (see Section 3.6.2 for details).

For more information, refer to the application note *Arm TrustZone features for STM32L5, STM32U3, and STM32U5 Series* (AN5347).

3.6 Other resource isolations



These are hardware mechanisms offering an additional level of isolation on top of the TrustZone technology.

3.6.1 Temporal isolation using secure hide protection (HDP)

When the TrustZone security is enabled (TZEN = 1), the embedded flash memory allows an HDP area per watermarked-secure area of each bank (4-Kbyte page granularity) to be defined. The code executed in this HDP area, with its related data and keys, can be hidden after boot until the next system reset.

The hide protection principle is pictured in *Figure 8*.

Figure 8. Flash memory secure HDP area

When the HDPx (x=1,2) area is enabled and the corresponding HDPx_ACCDIS byte is different than its reset value 0xA3, data read, write and instruction fetch on the area defined by SECWMx_STRT and HDPx_END option bytes, are denied until the next device reset. The end of the HDPx areas can be extended (dynamically by the application) thanks to FLASH_SECHDPEXTR register. Refer to *Section 7.5.3: Secure hide protection (HDP)* and *Section 7.5.4: Secure hide protection extension (HDP extension)* for details.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

The HDP area can be resized by a secure application if the area is not hidden, and if RDP level ≠ 2.

3.6.2 Resource isolation using Cortex privileged mode

In parallel to the TrustZone isolation described in *Section 3.5*, the hardware and software resources of STM32U3 series devices can be partitioned so that they are restricted to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, available even if TrustZone is deactivated (TZEN = 0), critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

Memory and peripheral privileged allocation using MPU

The Cortex-M33 MPU divides the unified memory into eight regions, each aligned to a multiple of 32 bytes. Each memory regions can be programmed to generate faults when accessed inappropriately by unprivileged software.

Memory and peripheral privileged allocation using GTZC

For the Cortex-M33 master, to complement the coarse isolation provided by the MPU, the GTZC reinforces, in a flexible way, the isolation between privileged and unprivileged tasks, for peripherals and selected memories.

For masters other than the Cortex-M33, the GTZC can assign them as unprivileged initiators, automatically protecting resources defined as privileged against this master.

Securing peripherals with TZSC (privileged-only)

In the devices, a peripheral is either securable privileged-only through GTZC, or is natively privileged-aware:

- A securable privileged-only peripheral or memory is protected by an AHB/APB firewall gate that is controlled by the TZSC.
- A privileged-aware peripheral or memory is connected directly to the AHB or APB interconnect, implementing a specific behavior such as a subset of registers or a memory area is privilege-only.

When such peripheral is made privileged-only with GTZC, if it is master on the interconnect (SDMMC), it automatically issues privileged transactions. Privilege-aware masters like GPDMA, drive privileged signal in the AHB interconnect according to their internal privileged mode, independently to the GTZC.

The list of securable peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

Securing memories with TZSC and MPCBB (privileged-only)

The GTZC provides the capability to configure the privilege level of embedded SRAM blocks, programming the MPCBB resources defined in *Section 3.5.4*.

Error management (privileged-only)

- Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal unprivileged read and write accesses.
- The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write.
- When an illegal unprivileged access occurs, no bus error is generated, except when this access is an instruction fetch, accessing a privileged memory or a peripheral register.

Managing security in privileged-aware peripherals

TrustZone-aware peripherals also implement privileged-only access mode. The privileged protection is valid even if TZEN = 0:

Embedded flash memory

By default all embedded flash registers can be read or programmed in both privileged and unprivileged modes.

When secure privileged bit SPRIV is set in FLASH_PRIVCFGR, reading and writing the flash secure registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is deactivated (TZEN = 0).

When nonsecure privileged bit PRIV is set in FLASH_PRIVCFGR, reading and writing the flash nonsecure registers are possible only in privileged mode.

Regarding privileged protection of the embedded flash memory, the devices offer the following features:

- The system flash memory can be accessed both in privileged and unprivileged modes.
- Each watermark-based secure area, including its secure HDP area, is accessible in secure-privileged and secure-unprivileged mode, if applicable.
- Each 4-Kbyte page of the embedded flash memory can be programmed on-the-fly as privileged only, using the block-based privileged configuration registers FLASH_PRIV1BBRx and FLASH_PRIV2BBRx. An unprivileged page is accessible by a privileged or unprivileged access.

Note: Switching a page from privileged to unprivileged does not erase the content of the page.

When applicable, an erase or program operation is always available to privileged code, and is available to unprivileged code only for unprivileged pages or unprivileged memory.

Direct memory access controllers (GPDMA)

When a DMA channel x is defined as privileged (PRIVx = 1 in GPDMA_PRIVCFGR), special rules apply when accessing privileged/unprivileged source or destination. Those rules are summarized in *Table 12*.

Table 12. DMA channel use (privilege)

Destination	Privileged DMA channel x (PRIVx = 1)		Unprivileged DMA channel y (PRIVy = 0)	
	Privileged source	Unprivileged source	Privileged source	Unprivileged source
Privileged	OK		Transfer blocked(1)	
Unprivileged			Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros.

See *Section 15: General purpose direct memory access controller (GPDMA)* for more details.

Power control (PWR)

By default, after a power-on or a system reset, all PWR registers but PWR_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

When secure privileged bit SPRIV is set in PWR_PRIVCFGR, reading and writing the PWR securable registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

When nonsecure privileged bit NSPRIV is set in PWR_PRIVCFGR, reading and writing the PWR nonsecure registers are possible only in privileged mode.

See *Section 9: Power control (PWR)* for details.

Secure clock and reset (RCC)

By default, after a power-on or a system reset, all RCC registers but RCC_PRIVCFGR can be read or written in both privileged and unprivileged modes.

When the secure privileged bit SPRIV is set in RCC_PRIVCFGR, reading and writing the RCC securable bits are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

When nonsecure privileged bit NSPRIV is set in RCC_PRIVCFGR, reading and writing the RCC nonsecure bits are possible only in privileged mode.

See *Section 10: Reset and clock control (RCC)* for details.

Real time clock (RTC)

By default after a backup domain reset, all RTC registers but RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

When PRIV bit is set in privileged-only RTC_PRIVCFGR:

Writing the RTC registers is possible only in privileged mode.

Reading the RTC_SECCFGR, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privileged and unprivileged modes.

All the other RTC registers can be read only in privileged mode.

When PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode to some RTC registers by setting dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRV or ALRBPRIV.

See *Section 43: Real-time clock (RTC)* chapter for details.

Tamper and backup registers (TAMP)

By default after any backup domain reset, all TAMP registers but TAMP_PRIVCFGR can be read or written in both privileged and unprivileged modes.

When PRIV bit is set in privileged-only TAMP_PRIVCFGR:

- Writing the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters that have their own protection setting.
- Reading the TAMP_SECCFGR or TAMP_PRIVCFGR is always possible in privilege and unprivilege modes. All the other TAMP registers can be read only in privilege mode, except for the backup registers and the monotonic counters that have their own protection setting.

The application can also:

- make TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR
- increase security for two of the three protection zones in backup registers, using BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:
  - Make protection zone 1 read privileged, write privileged.
  - Make protection zone 2 read privileged or unprivileged, write privileged.
  - Protection zone 3 is always read and write privileged or unprivileged.

General-purpose I/Os (GPIO)

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

Extended interrupts and event controller (EXTI)

The EXTI peripheral is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in the privileged-only EXTI_PRIVCFGR1 register. When an input event is configured as privileged, only a privileged application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

The security configuration in EXTI_PRIVCFGR1 can be globally locked after reset in EXTI_LOCKR.

See *Section 17: Extended interrupts and event controller (EXTI)* for more details.

System configuration controller (SYSCFG)

All SYSCFG registers can be read and written in both privileged and unprivileged modes, except:

- FPUSEC bit in SYSCFG_SECCFGR registers (privileged only)
- SYSCFG registers for CPU configuration: SYSCFG_CSLOCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR

See *Section 13: System configuration controller (SYSCFG)* for more details.

3.7 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

3.7.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex-M33 operating mode (privileged, unprivileged)
- data/instruction fetch

The memory map and the programming of the nonsecure and secure MPUs split memory into regions (up to eight for the nonsecure, and up to twelve for the Trustzone). Secure MPU is only available when TrustZone is activated.

3.7.2 Embedded flash memory write protection

The embedded flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes, writing the start and end addresses: two write-protected areas can be defined in each bank, with the granularity of a 4-Kbyte page.

WRP areas can be modified through option byte changes unless the corresponding FLASH_WRPxA/BR has its UNLOCK option bit cleared (meaning ROM emulation). UNLOCK can be set only when regressing from RDP level 1 to level 0.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.7.3 Tamper detection and response

Tamper detection sources

The devices support five input pins, allowing five static tamper inputs.

The tamper detection is functional in all system operating modes (Run, Sleep, Stop, Standby, or Shutdown), and in V_{BAT} mode.

Two modes are supported: edge detection, for which no clock is needed, and level detection with filtering. In this last case, the filtering is performed using either LSI or LSE clock (only LSE is available in Shutdown and V_{BAT} modes), and the tamper detection event is generated when either 2, 4 or 8 consecutive samples are observed at the selected level.

Note: Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in *Table 446: TAMP interconnection*. Refer to *Section 44: Tamper and backup registers (TAMP)* for more details.

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.

- Erase device secrets if the corresponding TAMPxPOM bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in SAES, AES, HASH, and CCB
  - asymmetric keys stored in PKA SRAM, erased when V_{DD} is present
  - other secrets stored in SRAM2 and CPU instruction cache memory (SRAM2 erased when V_{DD} is present)
  - nonvolatile information used to derive the DHUK in SAES is zeroed until complete SRAM2 erase
  - ICACHE erased when V_{DD} is present

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

Note: Device secret erase is also triggered by setting BKERASE in TAMP_CR2, or by performing an RDP regression as defined in Section 3.10.1.

Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxPOM bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such situation, when the tamper flag is raised, access to below secrets is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, SRAM2: read-as-zero, write-ignored
- AES, SAES, CCB, and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)

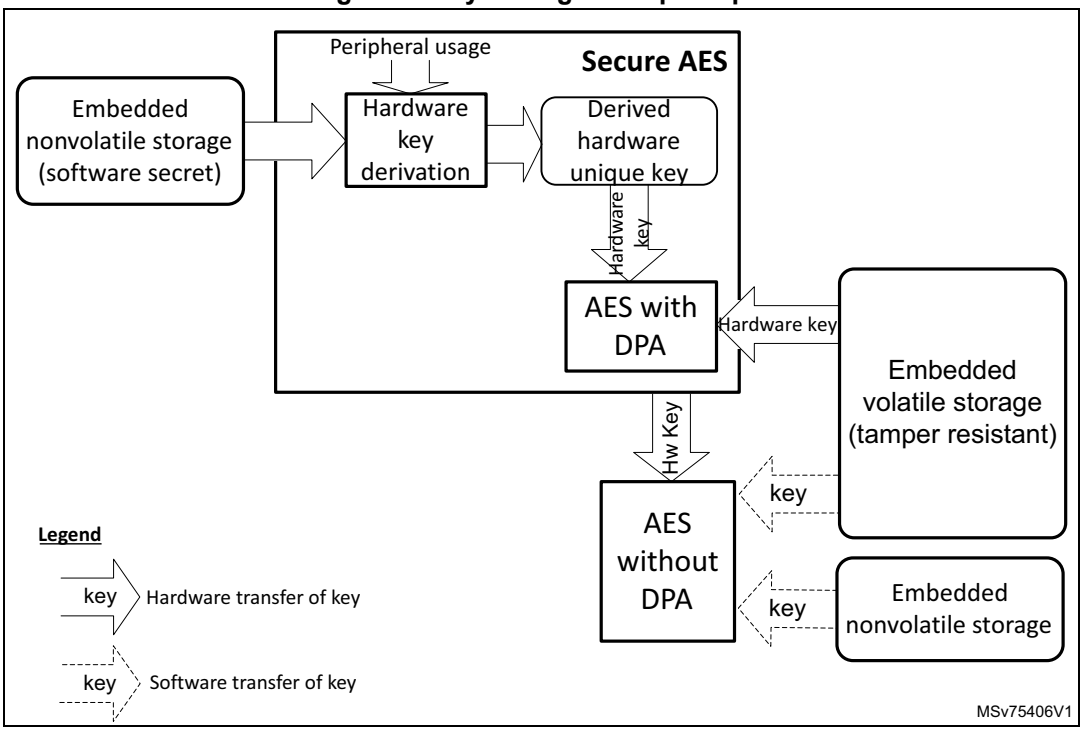
Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to such a tamper flag, an IWDG reset triggers automatically the erase of secrets.

Tamper detection and low-power modes

The effect of low-power modes on a tamper detection are summarized in *Table 450: Effect of low-power modes on TAMP*.



3.8 Secure storage

A critical feature of any security system is how long-term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

Figure 9 shows how the key management service application can use the AES engine, for example, to compute external image decryption keys. A nonvolatile key can be stored in the embedded secure HDP area (see *Section 3.6.1*), while volatile key storage consists in the battery-powered, tamper-protected SRAM or registers in TrustZone-aware TAMP.

Figure 9 also shows keys that are manipulated by software, or keys that are managed only by hardware (like DHUK). More information on those hardware keys can be found in *Section 3.8.1*.

Figure 9. Key management principle

Tamper protection is detailed in *Section 3.7.3*, while TAMP TrustZone features are briefly described in *Section 3.5.5*.

3.8.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys, using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in case of tamper.

There are three different sources of hardware secret keys:

- DHUK: derived keys based on 256-bit nonvolatile device unique secret in flash memory, also known as Root Hardware Unique Key (RHUK). The generation of this key takes into account the TrustZone state and key use state (KMOD).

  Note: DHUK is the same for all devices when RDP = 0 (debug/development mode).
- BHK: 256-bit application key stored in tamper-resistant volatile storage in TAMP

  This key is written at boot time, then read/write locked to application until next reset.
- XORK: result of an XOR of BHK and DHUK

These keys can be used:

- as normal key, loading in write-only key registers (software key mode)
- as encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as encryption/decryption key for another key, to be used in a faster AES engine (shared key mode)

3.8.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see *Section 54.1: Unique device ID register (96 bits)*).

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (RHUK) can be used (see *Section 3.8.1*).

3.9 Cryptographic engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the U.S.A, BSI for Germany or ANSSI for France. Those algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The cryptographic engines embedded in STM32 reduce the weaknesses on the implementation of critical cryptographic functions, preventing, for example, the use of weak cryptographic algorithms and key sizes. They also enable lower processing times and lower power consumption when performing cryptographic operations, offloading those computations from Cortex-M33. This is especially true for asymmetric cryptography.

For product certification purpose, ST can provide certified device information on how these security functions are implemented and validated.

For more information on cryptographic engine processing times, refer to their respective sections in the reference manual.

3.9.1 Cryptographic engines features

Table 13 lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available (both can be reserved to secure application only).

Note: Additional operations can be added using the firmware.

The PKA can accelerate asymmetric cryptographic operations (like key pair generation, ECC scalar multiplication, point on curve check). See Section 34: Public key accelerator (PKA) for more details.

Table 13. Accelerated-cryptographic operations

Operations	Algorithm	Specification	Key lengths (in bit)	Modes
Get entropy	RNG	NIST SP800-90B(1)	N/A	Software and hardware modes running in parallel(2)
Encryption, decryption	AES(3)	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D	128, 256	GCM, CCM
Cipher-based message authentication code		NIST SP800-38D	128, 256	GMAC
Checksum	SHA-1	FIPS PUB 180-4	N/A	Digest 160-bit
Cryptographic hash	SHA-2			SHA-224, SHA-256, SHA-384, SHA-512
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long (> 64 bytes)	-
Encryption/decryption key-pair generation(4)	RSA	IETF RFC 8017 NIST SP800-56B	Up to 4160	RSAES-OAEP
Signature(4) with hashing Signature verification	RSA	IETF RFC 8017 FIPS PUB 186-4	Up to 4160	PKCS1-v1_5, PSS
	ECDSA	ANSI X9.62 IETF RFC 7027 FIPS PUB 186-4	Up to 640	Refer to the table ‘Family of supported curves for ECC operations’ in *Section 34: Public key accelerator (PKA)* for details.
Key agreement	ECDH	ANSI X9.42		

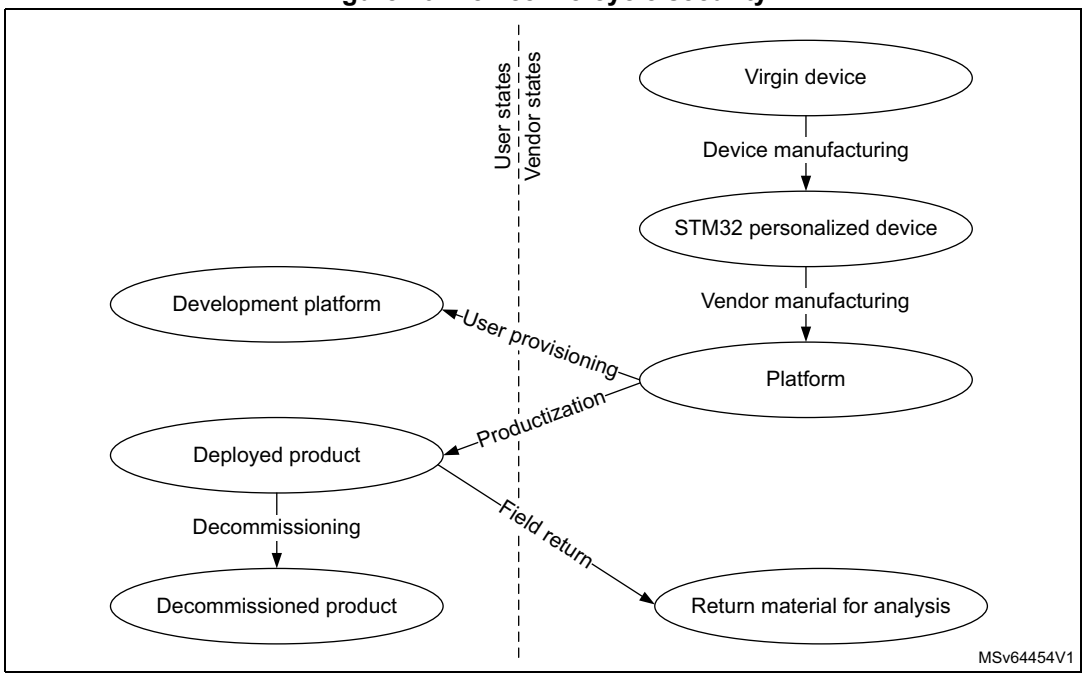
1. Certifiable using STMicroelectronics reviewed documents.
2. Random numbers distribution to SAES and PKA using a dedicated hardware bus.
3. Protected against side-channel and timing attacks in SAES (see *Section 3.9.2*).
4. Private key cryptography protected against side-channel and timing attacks.

Note: Binary curves, Edwards curves, and Curve25519 are not supported by the PKA.

3.9.2 Secure AES co-processor (SAES)

The devices provide an additional on-chip hardware AES encryption and decryption engine, that implements counter-measures and mitigations against power and electromagnetic sidechannel attacks.

Clocked by the AHB bus clock and a dedicated kernel clock, SAES is slower than the AES, in order to provide best-in-class side-channel protections. The SAES engine supports 128-bit or 256bit key in electronic code book (ECB), cipher block chaining (CBC), (CTR), (GCM), (CCM), (GMAC) modes.



As shown in *Section 3.8*, the SAES can be used for extra-secure on-chip storage for sensitive information. It can also be made secure-only.

For more information, refer to *Section 32: Secure AES coprocessor (SAES)*.

3.10 Product life-cycle

A typical IoT device life-cycle is summarized in the figure below. For each step, the devices propose secure life-cycle management mechanisms embedded in the hardware.

Figure 10. Device life-cycle security

More details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in *Table 14*.

Table 14. Main product life-cycle transitions

Transitions	Description
Device manufacturing	STMicroelectronics creates new STM32 devices, always checking for manufacturing defects. During this process STM32 is provisioned with ROM firmware, secure firmware install (SFI) unique key pair, and a public ID.
Vendor manufacturing	One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“production” transition) or he/she can use the platform for software development (“user provisioning” transition).
Production	The end-user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.
User provisioning	Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.
Field return or decommissioning	These are one-way transitions, with devices kept in user premises or returned to the manufacturer. In both cases, all data including user data is destroyed, therefore the devices lose the ability to operate securely (like connecting to a managed IoT network).

The features described hereafter contribute to secure the device life-cycle.

3.10.1 Life-cycle management with readout protection (RDP)

The readout protection mechanism (full hardware feature) controls the access to the devices debug, test and provisioned secrets, as summarized in *Table 15*.

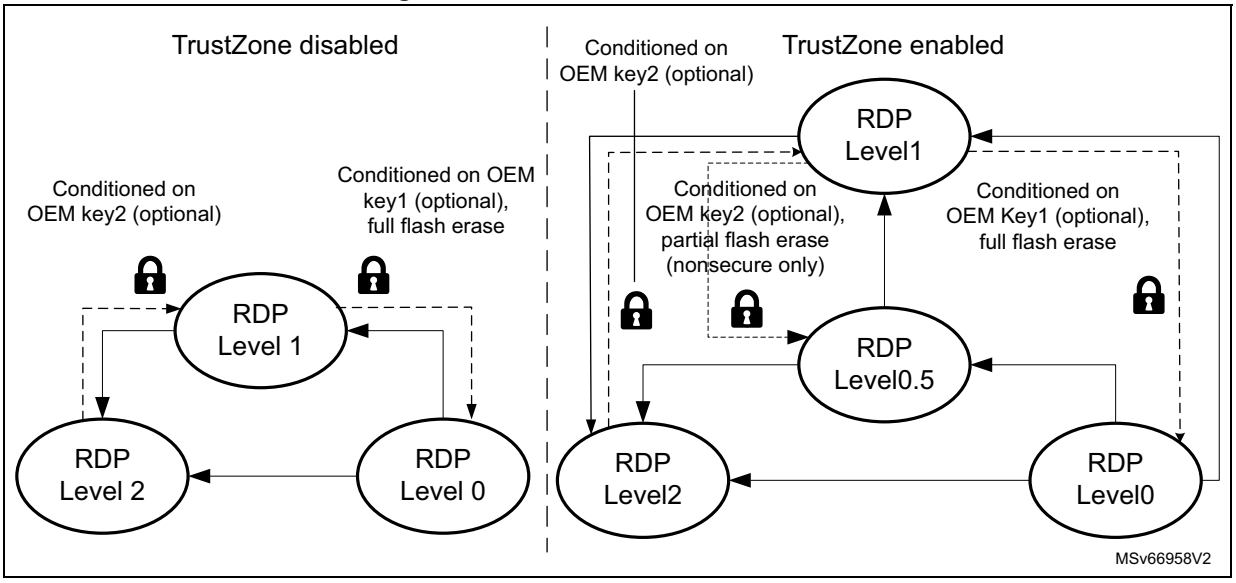


Table 15. Typical product life-cycle phases

RDP protection level		Debug	Comments
Level 0	Device open	Secure(1) and nonsecure	Boot address must target a secure area when TrustZone is enabled (secure SRAM, secure flash memory, RSS in system flash memory). Both OEM1 and OEM2 unlocking keys can be provisioned in the flash memory user options. The DHUK in the SAES peripheral is the same for all devices.
Level 0.5(2)	Device partially closed (closed-secure)	Nonsecure only	Boot address must target a secure area when TrustZone is enabled (secure user or system flash memory). Boot on SRAM is not permitted. Access to nonsecure flash memory is allowed when debug is connected. Both OEM1 and OEM2 unlocking keys can be provisioned in the flash memory user options. The DHUK is different for every device.
Level 1	Device memories protected	Nonsecure only (conditioned)	Boot address must target the secure user flash memory. Accesses to nonsecure flash memory, encrypted flash memory, SRAM2, and backup registers are **not allowed** when debug is connected. Both OEM1 and OEM2 unlocking keys can be provisioned in the flash memory user options. The DHUK is different for every device.
Level 2	Device closed	None (JTAG fuse)	Boot address must target the user flash memory (secure if TZEN = 1). Option bytes are read-only, hence RDP level 2 cannot be changed, unless the OEM2 unlocking key is activated (see *Table 16*). The DHUK is different for every device.

1. Debug is not available when executing RSS code.
2. Only applicable when TrustZone security is activated in the product.

The supported transitions, summarized in *Figure 11*, can be requested (when available) through the debug interface or via the system bootloader.

Figure 11. RDP level transition scheme

As shown in the previous figure, the user flash memory is automatically erased, either partially or in totality, during an RDP regression from RDP1. Those regressions can be conditioned to dedicated 128-bit password keys, if provisioned by the OEM (see next subsection). During the regression from RDP level 1 to RDP level 0.5, only nonsecure embedded flash memory is erased, keeping functional, for example, the secure boot and the secure firmware update. In all regressions from level 1, the OTP area in the flash memory is kept, all SRAMS and targeted device secrets are erased. Hence, no secrets must be stored in the OTP as they are revealed after a regression to RDP level 0. These secrets, also erased as response to tamper, are defined in *Section 3.7.3*.

Note: Enabling TrustZone using the option byte TZEN is only possible when RDP level is 0.

For more details on RDP, refer to *Section 7: Embedded flash memory (FLASH)*.

RDP unlocking sequences

The use of the two OEM password keys described in the last figure is further described hereafter.

Note: The devices support both permanent RDP level 2 (legacy mode) or password-based RDP level 2 regression to level 1. This level 2 regression does not erase the application code, and it does not change the RDP level 1 protections in place.

Details on the password-based regression can be found in *Table 16*.

Table 16. OEM1/2 RDP unlocking methods

OEM1 password options			OEM2 password options		
OEM1 LOCK	**Initial RDP level**	**RDP regression**	**OEM2 LOCK**	**Initial RDP level**	**RDP regression**
1	1	Regression to level 0 possible only through OEM1 unlock sequence (see below)	1	1	Regression to level 0.5 possible only through OEM2.1 unlock sequence (see below)
				2	Automatic regression to level 1 triggered upon successful OEM2.2 unlock sequence (see below)
0		Regression to level 0 always granted	0	1	Regression to level 0.5 always granted
				2	Regression to level 1 never granted RDP remains a permanent state.

Note: RDP regression with OEM key is described in section OEM1 RDP lock mechanism and OEM2 RDP lock mechanism.

JTAG 32-bit device specific ID

Unless the JTAG port is deactivated (OEM2LOCK = 0 and RDP level = 2), a 32-bit device specific quantity can always be read though the JTAG port. This information is stored in DBGMCU_DBG_AUTH_DEVICE.

The OEM can use this 32-bit information to derive the expected OEM password keys to unlock this specific device.

3.10.2 Recommended option-byte settings

Most of the time, the user threat model focuses mainly on software attacks. In this case, it may be sufficient to keep the RDP level 1 as device protection.

For a more aggressive threat model, where the user fears physical attacks on the STM32 device, it is recommended to optimize the level of security by setting the RDP level 2.

The recommended settings are detailed below:

- If TrustZone is disabled (TZEN = 0)
  - RDP level 2
  - nonsecure boot address option bytes set in user flash memory
- If TrustZone is enabled (TZEN = 1)
  - RDP level 2
  - BOOT_LOCK = 1
  - secure boot address option bytes set in user secure flash memory

As described in the previous section, the customer can decide to allow any RDP level 2 part to regress to RDP level 1, provided the OEM Key2 has been successfully provisioned, and the OEM2LOCK option bit is set.

3.11 Access controlled debug

The device restricts access to embedded debug features, in order to guarantee the confidentiality of customer assets against unauthorized usage of debug and trace features.

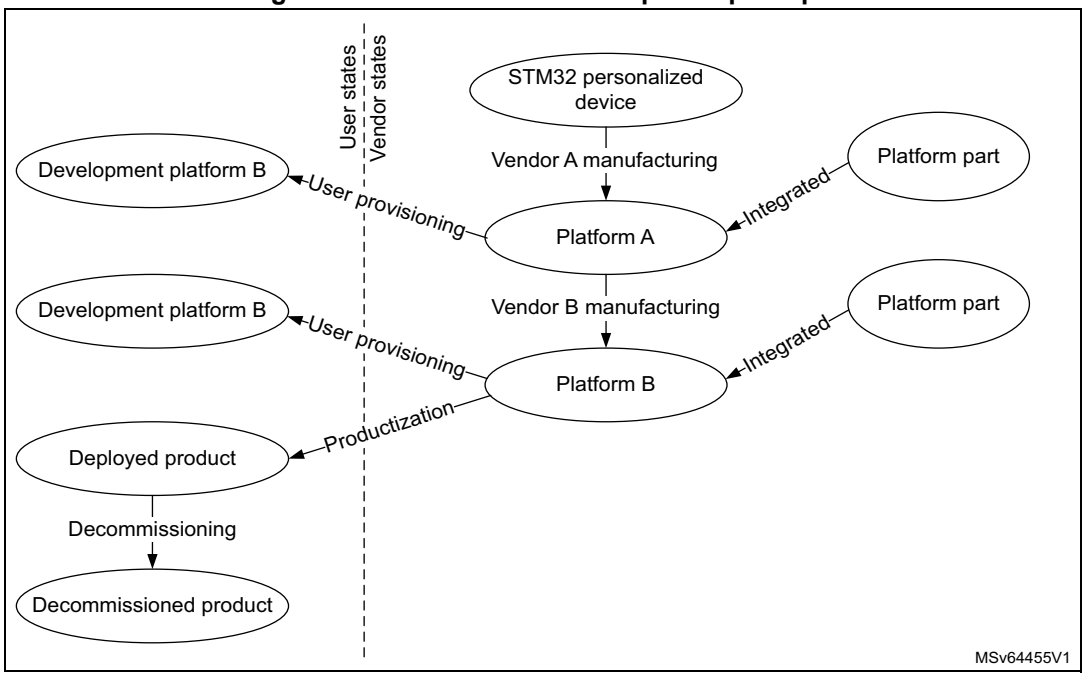
3.11.1 Debug protection with readout protection (RDP)

As described in *Section 3.10.1,* the hardware RDP mechanism automatically controls the accesses to the device debug and test. The protection of these debug features is defined in *Table 17*. Possible password-based regressions are described in *Section 3.10.1*.

Table 17. Debug protection with RDP

RDP protection level		Debug features protection
Level 0	Device open	Any debug(1)
Level 0.5(2)	Device partially closed	Secure debug is no longer available.
Level 1	Device memories protected	Nonsecure debug can no longer debug code and data stored in the embedded flash memory, the encrypted external flash memory, SRAM2, and backup registers.
Level 2	Device closed	JTAG is physically deactivated, unless it is kept operational only for password key injection (OEM2LOCK = 1). See *Section 3.10.1* for details.

1. Including ST engineering test modes, used for field returns.
2. Only applicable when TrustZone security is activated in the product.



3.12 Software intellectual property protection and collaborative development

Thanks to the software intellectual property protection and collaborative model, the devices allow the design of solutions integrating innovative third-party libraries.

Collaborative development is summarized on the figure below. Starting from a personalized device sold by STMicroelectronics, a vendor A can integrate a portion of hardware and software on a platform A, that can then be used by a vendor B, who does the same before deploying a final product to the end users.

Note: Each platform vendor can provision individual platforms for development not to be connected to a production cloud network (“Development Platform X”).

Figure 12. Collaborative development principle

The features described hereafter contribute to securing the software intellectual property within such a collaborative development.

3.12.1 Software intellectual property protection with RDP

As described in *Section 3.10.1,* the hardware RDP mechanism automatically controls the accesses to secrets provisioned in the device.

The protection of these secrets are defined in *Table 18*.

Table 18. Software intellectual property protection with RDP

RDP protection level		Secrets protection
Level 0	Device open	No special protections.
Level 0.5(1)	Device partially closed	All peripherals and memories mapped as secure during secure boot cannot be dumped, debugged, or traced
Level 1	Device memories protected	Data and code stored in embedded flash memory, SRAM2, and backup registers are no longer accessible through the debugger.
Level 2	Device closed	All data and code stored in the device cannot be dumped clear-text, debugged or traced.

1. Only applicable when TrustZone security is activated in the product.

3.12.2 Other software intellectual property protections

The device additional protections to software intellectual property are:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds.
- Non-invasive attacks, such as side channel attacks, are countered by not leaking secret information via side channels such as timing, power and EM emissions.

4 Boot modes

At startup, NBOOT0 and NSWBOOT0 option bits of the FLASH_OPTR register, and ADD[24:0] option bytes of the FLASH_BOOT0R, FLASH_BOOT1R or FLASH_SBOOT0R registers are used to select the boot memory address that includes:

- Boot from any address in user flash memory
- Boot from system memory (bootloader)
- Boot from any address in the embedded SRAM
- Boot from root security service (RSS)

The BOOT0 value may come from the BOOT0 pin or from an option bit depending on the value of a user option bit to free the GPIO pad if needed.

The bootloader, located in the system memory, is used to reprogram the flash memory by using USART, I2C, I3C, SPI, FDCAN, or USB in device mode through the DFU (device firmware upgrade).

Table 19 and *Table 20* detail the boot modes when TrustZone is disabled or enabled.

Table 19. Boot modes when TrustZone is disabled (TZEN = 0)

NBOOT0	BOOT0 pin	NSW BOOT0	Boot address option-byte selection	Boot area	ST programmed default value
-	0	1	ADD[24:0] in FLASH_BOOT0R	Nonsecure boot base address 0 defined by user option bytes in FLASH_BOOT0R	Flash memory: 0x0800 0000
-	1	1	ADD[24:0] in FLASH_BOOT1R	Nonsecure boot base address 1 defined by user option bytes in FLASH_BOOT1R	Bootloader: 0x0BF8 F000
1	-	0	ADD[24:0] in FLASH_BOOT0R	Nonsecure boot base address 0 defined by user option bytes in FLASH_BOOT0R	Flash memory: 0x0800 0000
0	-	0	ADD[24:0] in FLASH_BOOT1R	Nonsecure boot base address 1 defined by user option bytes in FLASH_BOOT1R	Bootloader: 0x0BF8 F000

When TrustZone is enabled by setting the TZEN option bit, the boot space must be in the secure area. The ADD[24:0] option bytes in FLASH_SBOOT0R are used to select the boot secure memory address.

A unique boot entry option can be selected by setting the BOOT_LOCK option bit. All other boot options are ignored.

Table 20. Boot modes when TrustZone is enabled (TZEN = 1)

BOOT_ LOCK	NBOOT0	BOOT0 pin	NSW BOOT0	RSS command	Boot address option-byte selection	Boot area	ST programmed default value
0	-	0	1	0	ADD[24:0] in FLASH_SBOOT0R	Secure boot base address 0 defined by user option bytes in FLASH_SBOOT0R	Flash memory: 0x0C00 0000
	-	1	1	0	N/A	RSS	RSS: 0x0FF8 0000
	1	-	0	0	ADD[24:0] in FLASH_SBOOT0R	Secure boot base address 0 defined by user option bytes in FLASH_SBOOT0R	Flash memory: 0x0C00 0000
	0	-	0	0	N/A	RSS	RSS: 0x0FF8 0000
	-	-	-	≠ 0	N/A	RSS	RSS: 0x0FF8 0000
1	-	-	-	-	ADD[24:0] in FLASH_SBOOT0R	Secure boot base address 0 defined by user option bytes in FLASH_SBOOT0R	Flash memory: 0x0C00 0000

The boot address option bytes are used to program any boot memory address. However, the allowed address space depends on flash memory read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced either in the secure flash memory or the nonsecure flash memory depending on the TrustZone security option as described in the table below.

Table 21. Boot space versus RDP protection

RDP	TZEN = 1	TZEN = 0
0	Any boot address	Any boot address
0.5	Boot address only in RSS: 0x0FF80000 or in secure flash memory 0x0C00 0000-0x0C0F FFFF Otherwise the boot address is forced to 0x0FF8 0000.	N/A
1		Any boot address
2		Boot address only in flash memory 0x0800 0000-0x080F FFFF Otherwise boot address forced is 0x0800 0000.

The BOOT0 value (either coming from the pin or the option bit) is latched upon reset release. It is up to the user to set NBOOT0 or BOOT0 values to select the required boot mode.

The BOOT0 pin or user option bit (depending on NSWBOOT0 in FLASH_OPTR) is also resampled when exiting Standby mode. Consequently, the BOOT0 pin or user option bit

must be kept in the required boot mode configuration in Standby mode. After the startup delay, the selection of the boot area is done before releasing the processor reset.

BOOT0 GPIO is configured as follows:

- In input mode during the complete reset phase, if the option bit NSWBOOT0 is set in FLASH_OPTR, and then switches automatically in analog mode after reset is released (BOOT0 pin)
- In input mode from the reset phase to the completion of the option byte loading, if the bit NSWBOOT0 is cleared in FLASH_OPTR (BOOT0 value coming from the option bit), and then switches automatically to the analog mode even if the reset phase is not complete

4.1 Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. Refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

4.2 Embedded root security services (RSS)

The embedded RSS are located in the secure information block, programmed by ST during production. The RSS, for example, enable the SFI (secure firmware installation), through the RSSe SFI (RSS extension firmware).

This feature allows the customer to produce the confidentiality of the firmware to be provisioned into the STM32, when production is sub-contracted to an untrusted third party.

The RSS are available on all devices, after enabling the TrustZone through the TZEN option bit. Refer to the application note *Overview secure firmware install (SFI)* (AN4992) for more details.

5 Global TrustZone controller (GTZC)

5.0.1 GTZC introduction

This section describes the global TrustZone controller (GTZC) block that contains the following subblocks:

- TZSC: TrustZone security controller

This subblock defines the secure/privileged state of slave peripherals. The TZSC informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.

- MPCBB: memory protection controller - block based

This subblock configures the internal RAM in a TrustZone-system product having segmented SRAM (pages of 512 bytes) with programmable-security and privileged attributes.

- TZIC: TrustZone illegal access controller

This subblock gathers all illegal access events in the system and generates a secure interrupt towards NVIC.

These subblocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes such as:

- on-chip RAM with programmable secure and/or privileged blocks (pages)
- AHB and APB peripherals with programmable security and/or privileged access
- off-chip memories with secure and/or privileged areas

5.0.2 GTZC main features

The GTZC main features are listed below:

- 3 independent 32-bit AHB interface for TZSC, TZIC and MPCBB
- TZIC accessible only with secure transactions
- Secure and nonsecure access supported for privileged and unprivileged part of TZSC and MPCBB
- Set of registers to define product security settings:
  - Secure/privileged blocks for internal SRAMs
  - Secure/privileged access mode for securable peripherals
  - Secure/privileged access mode for securable masters

GTZC TrustZone system architecture

The Armv8-M supports security per TrustZone-M model with isolation between:

- a secure world, where usually security sensitive applications are run and critical resources are located
- a nonsecure or public world (such as usual non secure operating system and user space)

The TrustZone architecture is extended beyond AHB and Armv8-M with:

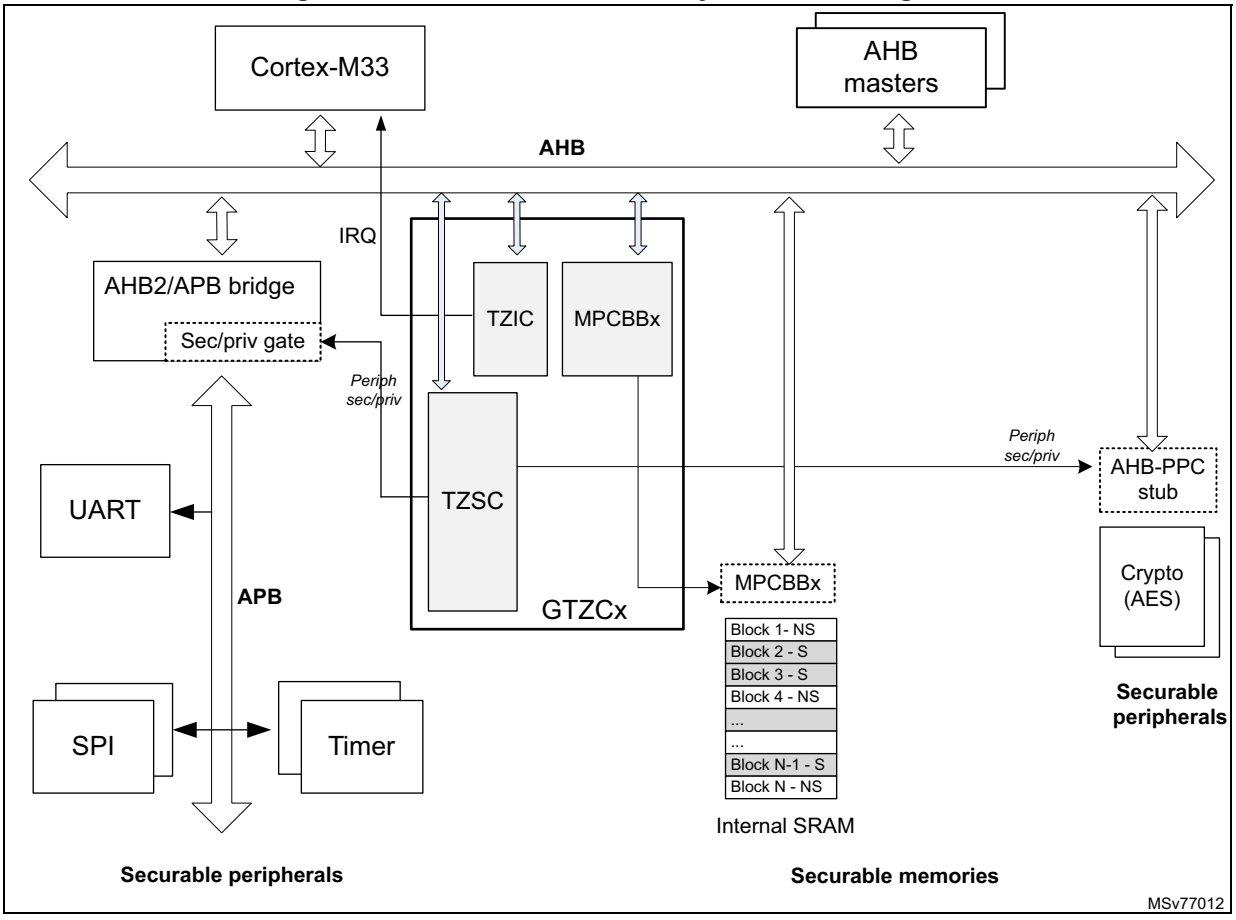
- AHB/APB bridge used as secure gate to block or propagate secure/nonsecure and privileged/unprivileged transaction towards APB agents

- PPC (peripheral protection controller) used as secure gate to block or propagate secure/nonsecure and privileged/unprivileged transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/non secure, privileged/ unprivileged access towards internal SRAMs

AHB and APB peripherals can be categorized as:

- **privileged**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (such as TZIC)
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **nonsecure and unprivileged**: peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA)

AHB securable masters can be configured in the TZSC to be secure/nonsecure and/or privileged/unprivileged.



Application information

The TZSC, MPCBB and TZIC can be used in one of the following ways:

- programmed during secure boot only, locked and not changed afterwards
- dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH region or secure SRAM. Same remark applies to the GTZC_TZSC_SECCFGRx/PRIVCFGRx registers that define secure/privileged state of each peripheral.

The Armv8-M security architecture with secure, securable and TrustZone-aware peripherals is shown in the figure below.

Figure 13. GTZC in Armv8-M subsystem block diagram

5.0.3 GTZC implementation

The STM32U3 series devices embed one instance of GTZC.

Table 22. GTZC features

GTZC subblocks	GTZC1
TZSC	X
TZIC	X
MPCBB subblock	MPCBB1/2

The table below shows the address offset of GTZC subblocks versus GTZC base address (refer to *Section 2.3.2* for GTZC1 base addresses).

Table 23. GTZC1 subblocks address offset

GTZC1 subblock	Address offset
GTZC1_TZSC	0x0
GTZC1_TZIC	0x400
GTZC1_MPCBB1	0x800
GTZC1_MPCBB2	0xC00

The table below describes the characteristics of the available MPCBB.

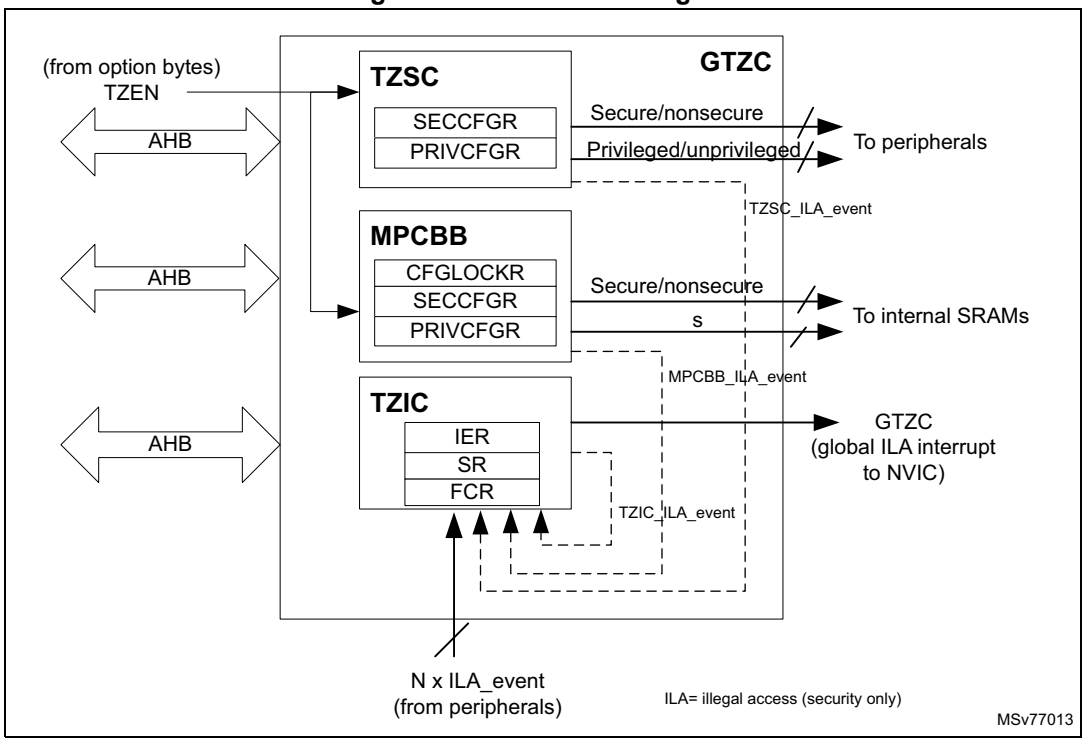
Table 24. MPCBB resource assignment

GTZC	MPC	Resource	Memory size (Kbytes)	Block size (bytes)	Number of blocks	Number of super-blocks
GTZC1	MPCBB1	SRAM1	192	512	384	12
	MPCBB2	SRAM2	64		128	4

5.1 GTZC functional description

5.1.1 GTZC block diagram

Figure 14 describes the combined feature of TZSC, MPCBB and TZIC. Each subblock is controlled by its own AHB configuration port.



The TZSC defines which peripheral is secure and/or privileged.The privileged configuration bit of a peripheral can be modified by a secure privileged transaction when the peripheral is configured as secure. Otherwise, a privileged transaction (nonsecure) is sufficient.

On the opposite, the secure configuration bit of a peripheral can be modified only with a secure privileged transaction if the peripheral is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The secure configuration bit of a given ram block can be modified only with a secure privileged transaction if the same RAM block is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The TZIC gathers illegal events generated within the system when an illegal access is detected. TZIC can then generate a secure interrupt towards the CPU if needed.

Figure 14. GTZC block diagram

5.1.2 Illegal access definition

Three different types of illegal access exist:

- Illegal nonsecure access

  Any nonsecure transaction trying to write a secure resource is considered as illegal and thus the addressed resource generates an illegal access interrupt for illegal write access and a bus error for illegal fetch access. However some exceptions exist on secure and privileged configuration registers: these later ones authorize non secure read access to secure registers (see GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx).

- Illegal secure access

  Any secure transaction trying to access nonsecure block in internal block-based SRAM is considered as illegal.

  Correct TZIC settings allows the capture of the associated event and then generates the GTZC_IRQn interrupt to the NVIC. This applies for read, write and execute access.

  Concerning the MPCBB controller, there is an option to ignore secure data read/write access on nonsecure SRAM blocks, by setting the SRWILADIS bit in the GTZC_MPCBBz_CR register. Secure read and write data transactions are then allowed on nonsecure SRAM blocks, while secure execution access remains not allowed.

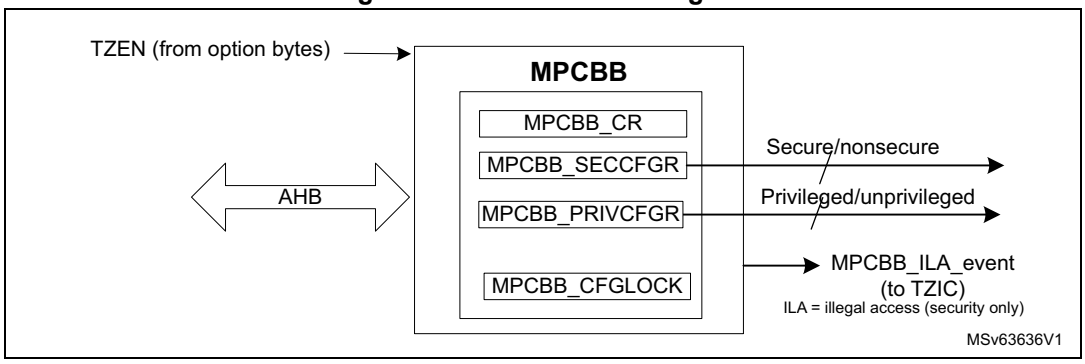
  Any secure execute transaction trying to access a nonsecure peripheral register is considered as illegal and generate a bus error.

- Illegal unprivileged access

  Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal read and write access. The

addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write. No bus error is generated. A bus error is generated when any unprivileged execute transaction tries to access a privileged memory.

5.1.3 TrustZone security controller (TZSC)



The TZSC is composed of a configurable set of registers, providing the following features:

- Control of secure and privileged state for all peripherals, done through:
  - GTZC_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals
  - GTZC_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals

5.1.4 Memory protection controller - block based (MPCBB)

The MPCBB is composed of a configurable set of registers allowing to define security and privileged policy for internal SRAM memories. The security and privileged policy can be individually configured per each 512-byte block of SRAM.

Figure 15. MPCBB block diagram

In order to setup the MPCBB, the following actions are needed (for example at boot time):

- Secure firmware must define which memory blocks are secure by setting the correct bits in GTZC_MPCBBz_SECCFGRx.
- Privileged firmware must define which memory blocks are privileged by setting the correct bits in GTZC_MPCBBz_PRIVCFGRx.

A MPCBB super-block is made of 32 consecutive blocks. For each super-block, secure application can lock all related security/privileged bits using the correct bits in GTZC_MPCBBz_CFGLOCKR1. This lock remains active until the next system reset.

*Note: The block size is 512 bytes.The super-block size is 512 * 32 = 16 Kbytes.*

5.1.5 TrustZone illegal access controller (TZIC)

The TZIC concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 1).

TZIC allows the trace (flag) of which event trigged the secure illegal access interrupt. Register masks (GTZC_TZIC_IERx) are available to filter unwanted event. On unmasked illegal event, TZIC generates the GTZC_IRQn interrupt to the NVIC.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC_TZIC_SRx and GTZC_TZIC_FCRx). The reset value of mask registers (GTZC_TZIC_IERx) is such that all events are masked.

5.1.6 Power-on/reset state

The power-on and reset state of the TZSC clear to 0 all bits of GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx, meaning that all securable peripherals are respectively set to nonsecure and unprivileged.

For internal SRAMx (x = 1 to 2), all GTZC_MPCBBz_SECCFGRx and GTZC_MPCBBz_PRIVCFGRx are set:

- to 0xFFFF FFFF, making these internal memories block secure and privileged by default when TrustZone security is enabled at system level (TZEN = 1).
- to 0x0000 0000, making these internal memories block nonsecure and unprivileged by default when TrustZone security is disabled at system level (TZEN = 0)

Secure boot code can then program the security settings, making components secure or not as needed.

5.1.7 GTZC interrupts

TZIC is a secure peripheral, thus it systematically generates an illegal access event when accessed by a nonsecure access. The MPCBB and TZSC are TrustZone-aware peripherals, meaning that secure and nonsecure registers co-exist within the peripheral.

Table 25. GTZC interrupt request

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
GTZC	Illegal access	All flags in GTZC_TZIC_SRx	All bits in GTZC_TZIC_IERx	Write 1 in the bit GTZC_TZIC_FCRx	Yes	Yes	No

5.2 GTZC1 TZSC registers

All registers are accessed only by words (32-bit).

5.2.1 GTZC1 TZSC control register (GTZC1_TZSC_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LCK**: Lock GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx configuration until next reset

This bit is cleared by default and once set, it cannot be reset until system reset.

0: Configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx registers not locked

1: Configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx registers locked

5.2.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1)

Address offset: 0x010

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC1_TZSC_PRIVCFGR register bit is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

Bit 22 **RAMCFGPRIV**: Privileged access mode for RAMCFG
0: Unprivileged
1: Privileged

Bit 21 Reserved, must be kept at reset value.

Bit 20 **OCTOSPI1_REGPRIV**: Privileged access mode for OCTOSPI1 registers
0: Unprivileged
1: Privileged

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **SDMMC1PRIV**: Privileged access mode for SDMMC1
0: Unprivileged
1: Privileged

Bit 16 **CCBPRIV**: Privileged access mode for CCB
0: Unprivileged
1: Privileged

Bit 15 **SAESPRIV**: Privileged access mode for SAES
0: Unprivileged
1: Privileged

Bit 14 **PKAPRIV**: Privileged access mode for PKA
0: Unprivileged
1: Privileged

Bit 13 **RNGPRIV**: Privileged access mode for RNG
0: Unprivileged
1: Privileged

Bit 12 **HASHPRIV**: Privileged access mode for HASH
0: Unprivileged
1: Privileged

Bit 11 **AESPRIV**: Privileged access mode for AES
0: Unprivileged
1: Privileged

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **ADC12PRIV**: Privileged access mode for ADC1 and ADC2
0: Unprivileged
1: Privileged

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ICACHE_REGPRIV**: Privileged access mode for ICACHE registers
0: Unprivileged
1: Privileged

Bit 5 Reserved, must be kept at reset value.

Bit 4 **TSCPRIV**: Privileged access mode for TSC
0: Unprivileged
1: Privileged

Bit 3 **CRCPRIV**: Privileged access mode for CRC
0: Unprivileged
1: Privileged

Bits 2:0 Reserved, must be kept at reset value.

5.2.8 GTZC1 TZSC register map

5.3 GTZC1 TZIC registers

All registers are accessed only by words (32-bit).

5.3.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only. This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VREFBUFIE	OPAMPIE	I3C1IE	SPI3IE	Res.	Res.	FDCAN1IE	LPTIM2IE	Res.
							rw	rw	rw	rw			rw	rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRSIE	I2C2IE	I2C1IE	UART5IE	UART4IE	USART3IE	Res.	SPI2IE	IWDGIE	WWDGIE	TIM7IE	TIM6IE	Res.	TIM4IE	TIM3IE	TIM2IE
rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VREFBUFIE**: Illegal access interrupt enable for VREFBUF
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 23 **OPAMPIE**: Illegal access interrupt enable for OPAMP
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 22 **I3C1IE**: Illegal access interrupt enable for I3C1
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 21 **SPI3IE**: Illegal access interrupt enable for SPI3
- 0: Interrupt disabled
- 1: Interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **FDCAN1IE**: Illegal access interrupt enable for FDCAN1 and FDCAN SRAM
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **LPTIM2IE**: Illegal access interrupt enable for LPTIM2
0: Interrupt disabled
1: Interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **CRSIE**: Illegal access interrupt enable for CRS
0: Interrupt disabled
1: Interrupt enabled

Bit 14 **I2C2IE**: Illegal access interrupt enable for I2C2
0: Interrupt disabled
1: Interrupt enabled

Bit 13 **I2C1IE**: Illegal access interrupt enable for I2C1
0: Interrupt disabled
1: Interrupt enabled

Bit 12 **UART5IE**: Illegal access interrupt enable for UART5
0: Interrupt disabled
1: Interrupt enabled

Bit 11 **UART4IE**: Illegal access interrupt enable for UART4
0: Interrupt disabled
1: Interrupt enabled

Bit 10 **USART3IE**: Illegal access interrupt enable for USART3
0: Interrupt disabled
1: Interrupt enabled

Bit 9 Reserved, must be kept at reset value.

Bit 8 **SPI2IE**: Illegal access interrupt enable for SPI2
0: Interrupt disabled
1: Interrupt enabled

Bit 7 **IWDGIE**: Illegal access interrupt enable for IWDG
0: Interrupt disabled
1: Interrupt enabled

Bit 6 **WWDGIE**: Illegal access interrupt enable for WWDG
0: Interrupt disabled
1: Interrupt enabled

Bit 5 **TIM7IE**: Illegal access interrupt enable for TIM7
0: Interrupt disabled
1: Interrupt enabled

Bit 4 **TIM6IE**: Illegal access interrupt enable for TIM6
0: Interrupt disabled
1: Interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TIM4IE**: Illegal access interrupt enable for TIM4
0: Interrupt disabled
1: Interrupt enabled

Bit 1 **TIM3IE**: Illegal access interrupt enable for TIM3
0: Interrupt disabled
1: Interrupt enabled

Bit 0 **TIM2IE**: Illegal access interrupt enable for TIM2
0: Interrupt disabled
1: Interrupt enabled

5.3.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2)

Address offset: 0x004

Reset value: 0x0000 0000

Secure privileged access only. This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 22 **RAMCFGF**: Illegal access flag for RAMCFG
- 0: No illegal access event
- 1: Illegal access event

Bit 21 Reserved, must be kept at reset value.

Bit 20 **OCTOSPI1_REGF**: Illegal access flag for OCTOSPI1 registers
- 0: No illegal access event
- 1: Illegal access event

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **SDMMC1F**: Illegal access flag for SDMMC1
- 0: No illegal access event
- 1: Illegal access event

Bit 16 **CCBF**: Illegal access flag for CCB
- 0: No illegal access event
- 1: Illegal access event

Bit 15 **SAESF**: Illegal access flag for SAES
- 0: No illegal access event
- 1: Illegal access event

Bit 14 **PKAF**: Illegal access flag for PKA
- 0: No illegal access event
- 1: Illegal access event

Bit 13 **RNGF**: Illegal access flag for RNG
0: No illegal access event
1: Illegal access event

Bit 12 **HASHF**: Illegal access flag for HASH
0: No illegal access event
1: Illegal access event

Bit 11 **AESF**: Illegal access flag for AES
0: No illegal access event
1: Illegal access event

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **ADC12F**: Illegal access flag for ADC1 and ADC2
0: No illegal access event
1: Illegal access event

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ICACHE_REGF**: Illegal access flag for ICACHE registers
0: No illegal access event
1: Illegal access event

Bit 5 Reserved, must be kept at reset value.

Bit 4 **TSCF**: Illegal access flag for TSC
0: No illegal access event
1: Illegal access event

Bit 3 **CRCF**: Illegal access flag for CRC
0: No illegal access event
1: Illegal access event

Bits 2:0 Reserved, must be kept at reset value.

5.3.8 GTZC1 TZIC status register 4 (GTZC1_TZIC_SR4)

Address offset: 0x01C

Reset value: 0x0000 0000

Secure privileged access only.

															rs

Bit 31 **SRWILADIS**: Secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction accesses a nonsecure block of the block-based SRAM (secure fetch on nonsecure block is always considered illegal).

0: Enabled, secure read/write access not allowed on nonsecure SRAM block

1: Disabled, secure read/write access allowed on nonsecure SRAM block

Bit 30 **INVSECSTATE**: SRAM1 clock security state

This bit is used to define the internal SRAM clock control in the RCC as secure or not.

0: SRAM clocks are secure if a secure area exists in the MPCBB, and nonsecure if there is no secure area.

1: SRAM clocks are nonsecure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: Lock the control register of the MPCBB until next reset

This bit is cleared by default and once set. It cannot be reset until system reset.

0: Control register not locked

1: Control register locked

5.4.2 GTZC1 SRAM1 MPCBB configuration lock register 1 (GTZC1_MPCBB1_CFGLOCKR1)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

				rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **SPLCKi**: Security/privilege configuration lock for super-block i (i = 11 to 0)
This bit is set by software, and can be cleared only by system reset.
0: GTZC1_MPCBB1_SECCFGRi and GTZC1_MPCBB1_PRIVCFGRi can be written.
1: Writes to GTZC1_MPCBB1_SECCFGRi and GTZC1_MPCBB1_PRIVCFGRi are ignored.

5.4.3 GTZC1 SRAM1 MPCBB security configuration for super-block x register (GTZC1_MPCBB1_SECCFGRx)

Address offset: 0x100 + 0x4 * x (x = 0 to 11)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x00000000 when TZEN = 0. Write access to this register is secure only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECi**: Security configuration for block i (i = 31 to 0)
Unprivileged write to this bit is ignored if PRIVi bit is set in GTZC1_MPCBB1_PRIVCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBB1_CFGLOCKR1.
0: Nonsecure access only to block i, belonging to super-block x. Secure access is also allowed if the SRWILADIS bit is set in GTZC1_MPCBBz_CR.
1: Secure access only to block i, belonging to super-block x.

5.4.4 GTZC1 SRAM1 MPCBB privileged configuration for super-block x register (GTZC1_MPCBB1_PRIVCFGRx)

Address offset: 0x200 + 0x4 * x (x = 0 to 11)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x00000000 when TZEN = 0. Write access to this register is privileged only. Any read is allowed.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
															rs

Bit 31 **SRWILADIS**: Secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction accesses a nonsecure block of the block-based SRAM (secure fetch on nonsecure block is always considered illegal).

0: Enabled, secure read/write access not allowed on nonsecure SRAM block

1: Disabled, secure read/write access allowed on nonsecure SRAM block

Bit 30 **INVSECSTATE**: SRAM2 clock security state

This bit is used to define the internal SRAM clock control in the RCC as secure or not.

0: SRAM clocks are secure if a secure area exists in the MPCBB, and nonsecure if there is no secure area.

1: SRAM clocks are nonsecure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: Lock the control register of the MPCBB until next reset

This bit is cleared by default and once set, it cannot be reset until system reset.

0: Control register not locked

1: Control register locked

5.5.2 GTZC1 SRAM2 MPCBB configuration lock register 1 (GTZC1_MPCBB2_CFGLOCKR1)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SPLCK3	SPLCK2	SPLCK1	SPLCK0
												rs	rs	rs	rs

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **SPLCKi**: Security/privilege configuration lock for super-block i (i = 3 to 0)
This bit is set by software, and can be cleared only by system reset.
0: GTZC1_MPCBB2_SECCFGRi and GTZC1_MPCBB2_PRIVCFGRi can be written.
1: Writes to GTZC1_MPCBB2_SECCFGRi and GTZC1_MPCBB2_PRIVCFGRi are ignored.

5.5.3 GTZC1 SRAM2 MPCBB security configuration for super-block x register (GTZC1_MPCBB2_SECCFGRx)

Address offset: 0x100 + 0x4 * x (x = 0 to 3)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x00000000 when TZEN = 0. Write access to this register is secure only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6 RAM configuration controller (RAMCFG)

6.1 RAMCFG introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1and SRAM2).

6.2 RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:

- Parity check on SRAM2
- Write protection (1-Kbyte granularity) on SRAM2
- SRAM software erase

6.3 RAMCFG functional description

6.3.1 Internal SRAMs features

- The STM32U3 devices feature 256 Kbytes SRAM, made of several blocks that can be powered down in Stop mode to reduce consumption:
  - SRAM1: 2 × 16-Kbyte + 5 × 32-Kbyte blocks (total 192 Kbytes)
  - SRAM2: 8-Kbyte + 24-Kbyte + 32-Kbyte blocks (total 64 Kbytes). In addition SRAM2 blocks can be retained in Standby mode according RRSB1, RRSB2, and RRSB3 bits setting in PWR_CR1.
  - Refer to power control (PWR_CR1 and PWR_CR2) for more details.
- All internal SRAMs are erased by hardware in case of Readout protection (RDP) level regression to level 0.5 or level 0. Refer to *Section 7.6.2: Readout protection (RDP)* for more details.
- Both SRAM1 and SRAM2 are erased when a system reset occurs if the corresponding SRAMx_RST option bit is selected in the flash memory user option bytes. Refer to *Section 7.4: FLASH option bytes* for more details.
- SRAM2 is protected by the tamper detection circuit, and is erased by hardware in case of tamper detection. Refer to *Section 44: Tamper and backup registers (TAMP)* for more details.
- The RAMCFG embeds the registers related to the internal SRAMs parity check, write protection and software erase.
- Parity check can be enabled for SRAM2.
- Both SRAM1 and SRAM2 can be erased by software.
- Write protection can be set on SRAM2, with 1-Kbyte granularity.

The table below summarizes the features supported by each internal SRAM.

Table 30. Internal SRAM features

SRAM feature	SRAM1 (192 Kbytes)	SRAM2 (64 Kbytes)
Optional retention in Standby mode	-	X
Erased with RDP regression	X	X
Erased or blocked by tamper detection	-	X
Optionally erased with system reset	X	X
Software erase	X	X
Parity check	-	X
Write protection	-	X

6.3.2 Parity error detection (SRAM2)

The parity error is supported by SRAM2. For each word, 4 bits are used for parity check (1 bit per byte) in order to increase memory robustness, as required for instance by Class B or SIL norms.

Parity can be controlled through PCE bit (RAMCFG_M2CR) and RAMCFG_M2PARKEYR:

- To enable parity: if parity is disabled, enable it by setting PCE bit.
- To disable parity: if parity is enabled, disable it with the following sequence:
  - Write 0xAE into PARKEY[7:0] (RAMCFG_M2PARKEYR).
  - Write 0x75 into PARKEY[7:0] (RAMCFG_M2PARKEYR).
  - Write 0 into PCE bit (1 to 0 transition is possible only if PARKEY[7:0] is unlocked).

When parity is enabled by SRAM2_PE user option bit, the PCE bit is automatically set (in RAMCFG_M2CR) after system reset. Refer to *Section 7.4: FLASH option bytes* for more details.

An interrupt or NMI is generated if enabled by the PEIE or PENMI bit in RAMCFG_M2IER. The failing address is stored in the PEA[31:0] in RAMCFG_M2PEAR if the ALE bit is set in RAMCFG_M2CR.

The parity error triggers a system break event in TIM1/15/16/17, if the SPL bit is set in SYSCFG_CFGR2.

6.3.3 Write protection (SRAM2)

The SRAM2 is made of 64 1-Kbyte pages. Each 1-Kbyte page can be write-protected by setting its corresponding PxWP (x = 0 to 63) bit in the RAMCFG_M2WPRx.

6.3.4 Software erase

SRAM erase can be requested by executing this software sequence:

1. Write 0xCA in RAMCFG_MxERKEYR.
2. Write 0x53 in RAMCFG_MxERKEYR.
3. Write 1 to the SRAMER bit in RAMCFG_MxCR.

SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is ongoing.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is written while an erase is ongoing, wait states are inserted on the AHB bus until the end of the erase operation. The SRAM is read as zero while an erase is ongoing.

6.4 RAMCFG in low-power modes

Table 31. Effect of low-power modes on RAMCFG

Mode	Description
Sleep	No effect. RAMCFG interrupts cause the device to exit the sleep mode.
Stop	The content of RAMCFG registers is kept. The parity check on SRAM2 is functional and parity error interrupt or NMI causes the device to exit from Stop 0, Stop1 and Stop 2 modes.
Standby	The RAMCFG peripheral is powered down and must be reinitialized after exiting Standby.

6.5 RAMCFG interrupts

The table below gives the list of RAMCFG interrupt requests.

Table 32. RAMCFG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop modes	Exit Standby mode
RAMCFG	Parity error	PED	PEIE = 1 and PENMI = 0	Write 1 in CPED	Yes	Yes(1)	No
NMI	Parity error	PED	PENMI	Write 1 in CPED	Yes	Yes(1)	No

1. Stop 0, Stop 1, and Stop 2 modes only.

6.6 RAMCFG registers

In registers described below, x refers to SRAM1 or SRAM2 when x = 1 or 2 respectively.

6.6.1 RAMCFG memory 1 control register (RAMCFG_M1CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rs								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY bitfield of RAMCFG_M1ERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

6.6.2 RAMCFG memory 1 interrupt status register (RAMCFG_M1ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rs				rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY bitfield of RAMCFG_M2ERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable in case of parity error

0: Failing address not stored in the SRAM2 parity error address registers

1: Failing address stored in the SRAM2 parity error address registers

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **PCE**: Parity check enable

This bit reset value is defined by the user option bit configuration. When set, this bit can be cleared by software only after writing the unlock sequence in RAMCFG_M2PARKEYR.

0: Parity check disabled

1: Parity check enabled

6.6.4 RAMCFG memory 2 interrupt enable register (RAMCFG_M2IER)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PENMI	Res.	Res.	PEIE
												rs			rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PENMI**: Parity error NMI
This bit is set by software and cleared only by a global RAMCFG reset.
0: NMI not generated in case of Parity error
1: NMI generated in case of Parity error
Note: if this bit is set, the RAMCFG maskable interrupt is not generated whatever PEIE value.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **PEIE**: Parity error interrupt enable
0: Parity error interrupt disabled
1: Parity error interrupt enabled

6.6.5 RAMCFG memory 2 interrupt status register (RAMCFG_M2ISR)

Address offset: 0x48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	PED	Res.
							r							r	

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation
0: No erase operation ongoing
1: Erase operation ongoing

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **PED**: Parity error detected
0: No Parity error detected
1: Parity error detected

Bit 0 Reserved, must be kept at reset value.

6.6.6 RAMCFG memory 2 parity error address register (RAMCFG_M2PEAR)

Address offset: 0x50

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PEA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **PEA[31:0]**: Parity error address

When the ALE bit is set in RAMCFG_MxCR, this bitfield is updated with the address corresponding to the parity error.

6.6.7 RAMCFG memory 2 interrupt clear register (RAMCFG_M2ICR)

Address offset: 0x54

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPED	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **CPED**: Clear parity error detected

Writing 1 to this flag clears PED bit in RAMCFG_MxISR. Reading this flag returns the PED value.

Bit 0 Reserved, must be kept at reset value.

6.6.8 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 63 to 32)
These bits are set by software and cleared only by a global RAMCFG reset.
0: Write protection of SRAM2 1-Kbyte page y is disabled.
1: Write protection of SRAM2 1-Kbyte page y is enabled.

6.6.10 RAMCFG memory 2 parity key register (RAMCFG_M2PARKEYR)

Address offset: 0x64

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PARKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PARKEY[7:0]**: Parity write protection key
The following steps are required to unlock the write protection of PCE in RAMCFG_MxCR.
1) Write 0xAE into PARKEY[7:0].
2) Write 0x75 into PARKEY[7:0].
Note: Writing a wrong key reactivates the write protection.

6.6.11 RAMCFG memory x erase key register (RAMCFG_MxERKEYR)

Address offset: 0x28 + 0x40 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of SRAMER in RAMCFG_MxCR.

1) Write 0xCA into ERASEKEY[7:0].

2) Write 0x53 into ERASEKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.12 RAMCFG register map

Table 33. RAMCFG register map and reset values

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

7 Embedded flash memory (FLASH)

7.1 FLASH introduction

The flash memory interface manages accesses to the flash memory, maximizing throughput to the CPU, instruction cache, and DMAs. It implements the flash memory erase and program operations, as well as the read and write protection mechanisms. It also implements the security and privileged access control features. It is optimized in terms of power consumption with dedicated modes when the MCU is in low-power modes.

7.2 FLASH main features

- Up to 1 Mbyte of flash memory supporting read-while-write capability (RWW)
- Memory organization
  - Dual bank architecture (bank 1 and bank 2)
  - Main memory: up to 512 Kbytes per bank
  - Information block: 104.5 Kbytes
- 64-bit wide data read with prefetch
- Standard and burst programming modes
- Read operations
- Program and erase operations only in range 1
- 10 kcycles endurance on all flash memory
- Page erase, bank erase and mass erase (both banks)
- Bank swapping: the user flash memory address mapping of each bank can be swapped.
- Product security activated by TrustZone option bit (TZEN)
- Device life cycle managed by readout protection option byte (RDP)
- 4 write protection areas (two per bank)
- TrustZone support:
  - 2 secure areas (1 per bank)
  - 2 secure HDP (hide protection) areas part of the secure areas (one per bank)
  - 2 secure HDP (hide protection) extension areas part of the secure areas (one per bank)
- Configurable protection against unprivileged accesses with flash page granularity
- Error code correction: 8-bit ECC per 64-bit double-word allowing 2-bit error detection and 1-bit error correction
- Option-byte loader
- Advanced low-power modes (low-power read mode, bank power-down mode)

7.3 FLASH functional description

7.3.1 Flash memory organization

The flash memory has the following main features:

- Capacity up to 1 Mbyte
- Dual-bank mode:
  - Up to 512 Kbytes per bank for main memory
  - 4-Kbyte page size
  - 72-bit wide data read and write (64 effective bits plus 8 ECC bits)
  - Page, bank and mass erase

The flash memory is organized as follows:

- Main memory block organized as two banks of up to 512 Kbytes each containing up to 128 pages of 4 Kbytes
- An information block containing:
  - 68 Kbytes for system memory. This area is immutable and reserved for use by STMicroelectronics. It contains the bootloader that is used to reprogram the flash memory through one of the user communication interfaces such as USB (DFU). The system memory is programmed by STMicroelectronics when the device is manufactured. For further details, refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).
  - 36 Kbytes immutable secure area containing the root security services (RSS and RSS library) developed by STMicroelectronics.
  - 512-byte OTP (one-time programmable) for user data (64 double-words). The OTP data cannot be erased and can be written only once. If only one bit is at 0, the entire double-word cannot be written anymore, even with the value 0x0000 0000 0000 0000.
  - Option bytes for user configuration. Unlike user flash memory and system memory, it is not mapped to any memory address and can be accessed only through the FLASH register interface.

The memory organization is based on a main area and an information block as shown in the table below.

Table 34. Flash module 1-Mbyte dual bank-organization

Flash memory area		Flash memory address	ADDR_ECC	Size (bytes)	Name
Main memory	Bank 1	0x0800 0000 - 0x0800 0FFF	0x00000 - 0x00FFF	4K	Page 0
		0x0800 1000 - 0x0800 1FFF	0x01000 - 0x01FFF	4K	Page 1
		...	...	...	...
		0x0807 F000 - 0x0807 FFFF	0x7F000 - 0x7FFFF	4K	Page 127
	Bank 2	0x0808 0000 - 0x0808 0FFF	0x00000 - 0x00FFF	4K	Page 0
		0x0808 1000 - 0x0808 1FFF	0x01000 - 0x01FFF	4K	Page 1
		...	...	...	...
		0x080F F000 - 0x080F FFFF	0x07F000 - 0x7FFFF	4K	Page 127

Table 34. Flash module 1-Mbyte dual bank-organization (continued)

Flash memory area		Flash memory address	ADDR_ECC	Size (bytes)	Name
Nonsecure information block	Bank 1	0x0BF8 F000 - 0x0BF9 77FF	0x04800 - 0x0CFFF	34K	System memory
	Bank 2	0x0BF9 7800 - 0x0BF9 FFFF	0x04800 - 0x0CFFF	34K	
	Bank 1	0x0BFA 0000 - 0x0BFA 01FF	0x0D000 -0x0D1FF	512	OTP area
Secure information block(1)	Bank 1	0x0FF8 0000 - 0x0FF8 3BFF	0x00000 - 0x03BFF	15K	RSS
	Bank 1	0x0FF8 3C00 - 0x0FF8 47FF	0x03C00 - 0x047FF	3K	RSS library
	Bank 2	0x0FF8 4800 - 0x0FF8 8FFF	0x00000 - 0x047FF	18K	RSS library

1. The secure information block is only accessible when TrustZone is active.

7.3.2 Error code correction (ECC)

Data in flash memory are 72-bit words: 8 bits are added per double-word (64-bit).
The ECC mechanism supports:

- One error detection and correction
- Two errors detection

When one error is detected and corrected, the ECCC flag (ECC correction) is set in FLASH_ECCCORR. If the ECCCIE bit is set, an interrupt is generated.

When two errors are detected, the ECCD flag (ECC detection) is set in FLASH_ECCDETR. In this case, a NMI is generated.

When an ECCC (respectively ECCD) error is detected, the address of the failing double-word and its associated bank are saved in ADDR_ECC[18:0] and BK_ECC in FLASH_ECCCORR (respectively FLASH_ECCDETR). ADDR_ECC[2:0] are always cleared.

When ECCC (respectively ECCD) is set, ADDR_ECC[18:0] and BK_ECC are not updated if a new ECCC (respectively ECCD) error occurs. FLASH_ECCCORR (respectively FLASH_ECCDETR) is updated only when ECCC (respectively ECCD) flags are cleared.

Note: For an erased flash line, one error is detected and corrected but two errors detection is not supported. When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared. As the ECC interface is shared by the two banks, if the same error is registered simultaneously, a physical bank 1 error is registered. Both errors are registered if one bank reports ECCD and the other bank ECCC.

The following addresses in the system flash memory are used to store words including ECC errors to allow run-time tests by software on ECC correction detection capability:

- 0x0BFA 0F00 (embeds a word with 1-bit error)
- 0x0BFA 0F80 (embeds a word with 2-bit error)

In case the second address is read, for instance by the debugger memory viewer, a NMI is generated.

7.3.3 Read access latency

To correctly read data from flash memory, the number of wait states (latency) must be correctly programmed in FLASH_ACR, according to the frequency of the CPU clock (HCLK) and the internal voltage range of the device V_{CORE} (refer to *Dynamic voltage scaling management* in PWR section).

The table below shows the correspondence between wait states and CPU clock frequency.

Table 37. Number of wait states according to CPU clock (HCLK) frequency (LPM = 0)

Wait states (WS) (latency)	HCLK (MHz)	
	V_{CORE} range 1	V_{CORE} range 2
0 WS (1 CPU cycle)	≤ 32	≤ 16
1 WS (2 CPU cycles)	≤ 64	≤ 32
2 WS (3 CPU cycles)	≤ 96	≤ 48

The flash memory supports a low-power read mode when setting the LPM bit in FLASH_ACR. The table below shows the correspondence between wait states and CPU clock frequency when LPM bit is set.

Table 38. Number of wait states according to CPU clock (HCLK) frequency (LPM = 1)

Wait states (WS) (latency)	HCLK (MHz)	
	V_{CORE} range 1	V_{CORE} range 2
0 WS (1 CPU cycle)	≤ 20	≤ 16
1 WS (2 CPU cycles)	≤ 40	≤ 32
2 WS (3 CPU cycles)	≤ 60	≤ 48
3 WS (4 CPU cycles)	≤ 80	NA
4 WS (5 CPU cycles)	≤ 96	NA

After reset, the CPU clock frequency is 12 MHz, 1 wait state (WS) is configured in FLASH_ACR, and the normal read mode is selected (LPM = 0).

Instruction prefetch

The Cortex-M33 fetches instructions and literal pools (constants/data) over the C-bus and through the instruction cache if it is enabled. The prefetch block aims at increasing the efficiency of C-bus accesses in case the instruction cache is enabled, by reducing the cache refill latency. Prefetch is efficient in case of sequential code. Prefetch in the flash memory allows the next sequential instruction line to be read from the flash memory while the current instruction line is being filled in instruction cache and executed by the CPU.

Prefetch is enabled by setting the PRFTEN bit in FLASH_ACR. This bit must be set only if at least 1 wait state is needed to access the flash memory.

Note: Prefetch tends to increase the code execution performance at the cost extra flash memory accesses. It must be used carefully in low-power applications.

When changing the CPU frequency, the software sequences detailed below must be applied in order to tune the number of wait states needed to access the flash memory.

Increase the CPU frequency

1. Program the new number of wait states to the LATENCY bits in FLASH_ACR.
2. Check that the new number of wait states is taken into account to access the flash memory by reading back FLASH_ACR.
3. Modify the CPU clock source by writing the SW bits in RCC_CFGR1.
4. Modify the CPU clock prescaler, if needed, by writing the HPRE bits in RCC_CFGR2.
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account, by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in RCC_CFGR1 and RCC_CFGR2.

Decrease the CPU frequency

1. Modify the CPU clock source by writing the SW bits in RCC_CFGR1.
2. Modify the CPU clock prescaler, if needed, by writing the HPRE bits in RCC_CFGR2.
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in RCC_CFGR1 and RCC_CFGR2.
4. Program the new number of wait states to the LATENCY bits in FLASH_ACR.
5. Check that the new number of wait states is used to access the flash memory by reading back FLASH_ACR.

The software sequences detailed below must be applied in order to modify the read mode.

From normal read mode to low-power read mode

1. Set the LPM bit in FLASH_ACR.
2. Check that the low-power read mode is activated by reading FLASH_ACR.

From low-power read mode to normal read mode

1. Reset the LPM bit in FLASH_ACR.
2. Check that the normal read mode is activated by reading FLASH_ACR.

7.3.4 Bank power-down mode

After reset, both banks are in normal mode. In order to reduce power consumption, each bank can be independently put in power-down mode by setting the PDREQx bit in FLASH_ACR.

Request entry in power-down mode for bank x

1. Check that bank x is not in power-down mode and no request to put it in power-down mode is pending (PDx bit in FLASH_SR and PDREQx bit in FLASH_ACR must be reset).
2. Unlock FLASH_PDKEYxR with correct keys.
3. Set the PDREQx bit in FLASH_ACR.
4. Check that the PDx bit in FLASH_SR is set. The PDREQx bit in FLASH_ACR is automatically reset, and FLASH_PDKEYxR is locked.

Note: If bank x is currently being accessed, the power-down request is delayed until the access is completed.

Requesting power-down entry for a bank already in power-down mode has no effect. The PDREQx bit in FLASH_ACR is automatically reset and FLASH_PDKEYxR is locked.

Return to normal mode

Any access to a bank in power-down mode automatically wakes up the bank. A penalty of 5 µs minimum is taken to wake up the bank.

Wake up bank 1 (respectively bank 2) is done in one of the following cases:

- Upon a valid read access to bank 1 (resp. bank 2)
- Upon a valid write access to bank 1(resp. bank 2)
- Upon a valid bank erase on bank 1 (resp. bank 2)

Waking up both bank 1 and bank 2 is done in one of the following cases:

- Upon a valid mass erase
- Upon an option-byte modification
- Upon an option-byte loading
- Upon system reset

Note: The software can reduce the flash bank wake-up time by enabling HSI16 before waking up the bank.

7.3.5 Flash memory program and erase operations

The embedded flash memory can be programmed using in-circuit programming or in-application programming.

The in-circuit programming (ICP) method is used to update the entire contents of the flash memory, using the JTAG, SWD protocol, or the bootloader to load the user application into the MCU. The ICP offers quick and efficient design iterations, and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, the in-application programming (IAP) can use any communication interface supported by the microcontroller (such as I/Os, USB, CAN, UART, I2C,or SPI) to download programming data into the memory. The IAP can be used to reprogram the flash memory while the application is running. Nevertheless, part of the application must have been previously programmed in the flash memory using ICP.

An ongoing flash memory operation does not block the CPU as long as the CPU does not access the same flash memory bank. Code or data fetches are possible on one bank while a write/erase operation is performed to the other bank (refer to *Section 7.3.9*).

On the contrary, during a program/erase operation to the flash memory, any attempt to read the same flash memory bank stalls the bus. The read operation proceeds correctly once the program/erase operation has been completed.

The MCU supports TrustZone that defines secure and nonsecure areas in the flash memory. All program and erase operations can be performed in secure mode through secure registers, or in nonsecure mode through nonsecure registers (refer to *Section 7.5*).

Program, erase and option change operations are only allowed in range 1. An error is reported when these operations are launched in range 2.

Unlock the secure/nonsecure flash control registers

After reset, write is not allowed in flash control registers (FLASH_SCR and FLASH_CR) in order to protect the flash memory against possible unwanted operations due (for example, electric disturbances).

The following sequence is used to unlock these registers:

1. Write KEY1 = 0x4567 0123 in FLASH_SKEYR or FLASH_KEYR.
2. Write KEY2 = 0xCDEF 89AB in FLASH_SKEYR or FLASH_KEYR.

Any wrong sequence locks up FLASH_SCR or FLASH_CR until the next system reset. In the case of a wrong key sequence, a bus error is detected and a hard fault interrupt is generated.

FLASH_CR (resp. FLASH_SCR) can be locked again by software by setting the LOCK bit in FLASH_CR (resp. FLASH_SCR).

Note: FLASH_CR and FLASH_SCR cannot be written when the BSY bits are set. Any attempt to write them with the BSY bits set, causes the AHB bus to stall until the BSY bits are cleared.

Wait for data-to-write flags (WDW)

WDW flags in FLASH_SR and FLASH_SSR are both set when a secure or nonsecure write access has been done in the write buffer. They are cleared when the BSY flags are set (meaning that the write buffer is freed and the programming operation actually starts in the flash memory), or in case of error.

It is software responsibility to ensure that the two words in the same double-word are all written.

FLASH secure and nonsecure busy flags

BSY flags in FLASH_SR and FLASH_SSR are both set when a secure or nonsecure FLASH operation is started:

- Erase operation: setting the STRT bit in FLASH_CR or FLASH_SCR
- Write operation: setting the PG bit in FLASH_CR or FLASH_SCR and writing a double-word in the flash memory
- Option-byte programming: setting the OPTSTRT (in FLASH_CR)

7.3.6 Flash main memory erase sequences

The flash memory erase operation can be performed at page level, bank level or on the whole flash memory (mass erase). Mass erase does not affect the information block (system flash, OTP and option bytes). The erase operation is either secure or nonsecure.

Page erase

To erase a page, follow the procedure below:

1. Check that voltage range is set to range 1.
2. Check that no flash memory operation is ongoing by checking the BSY bit and that the write buffer is empty by checking the WDW bit in the FLASH_SR or FLASH_SSR.
3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.

4. Set the PER bit and select the page to erase (PNB) with the associated bank (BKER) in FLASH_CR or FLASH_SCR.
5. Set the STRT bit in FLASH_CR or FLASH_SCR. Set the STRT by privilege code if targeted page is privileged.
6. Wait for the BSY bit to be cleared in FLASH_SR or FLASH_SSR.
7. Clear PER in FLASH_CR or FLASH_SCR if there is not anymore page erase request.

Bank 1 or bank 2 mass erase

To perform a bank mass erase, follow the procedure below:

1. Check that voltage range is set to range 1.
2. Check that no flash memory operation is ongoing by checking the BSY bit. Check that the write buffer is empty by checking the WDW bit in FLASH_SR or FLASH_SSR.
3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
4. Set the MER1 or MER2 bit (depending on the bank) in FLASH_CR or FLASH_SCR. Both banks can be selected in the same operation. In that case, it corresponds to a mass erase.
5. Set the STRT bit in FLASH_CR or FLASH_SCR. Set the STRT by privilege code if targeted banks are privileged.
6. Wait for the BSY bit to be cleared in FLASH_SR or FLASH_SSR.
7. The MER1 or MER2 bits can be cleared if no more bank erase is requested.

Mass erase

To perform a mass erase, follow the procedure below:

1. Check that voltage range is set to range 1.
2. Check that no flash memory operation is ongoing by checking the BSY bit. Check that the write buffer is empty by checking the WDW bit in FLASH_SR or FLASH_SSR.
3. Check and clear all nonsecure error programming flags due to a previous programming. If not, the PGSERR bit is set.
4. Set the MER1 bit and MER2 bits in FLASH_CR or FLASH_SCR.
5. Set the STRT bit in the FLASH_CR or FLASH_SCR.
6. Wait for the BSY bit to be cleared in the FLASH_SR or FLASH_SSR.
7. The MER1 and MER2 bit can be cleared if no more mass erase is requested.

Note: The internal oscillator HSI16 (16 MHz) is enabled automatically when the STRT bit is set, and disabled automatically when the STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR.

To erase a page, a bank or to perform a mass erase, software must have sufficient privilege (see Table 61 and Table 62).

STRT bit is cleared automatically at the end of erase or in case of error.

7.3.7 Flash memory programming sequences

The flash memory is programmed 72 bits at a time (64-bit data + 8-bit ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets the PROGERR flag in FLASH_SR or FLASH_SSR.

It is only possible to program double-word (2 × 32-bit data):

- Any attempt to write byte or half-word sets the SIZERR flag in FLASH_SR or FLASH_SSR.
- Any attempt to write a double-word that is not aligned with a double-word address sets the PGAERR flag in FLASH_SR or FLASH_SSR.

Flash programming

The flash memory programming sequence is as follows:

1. Check that voltage range is set to range 1.
2. Check that no flash main memory operation is ongoing by checking the BSY bit in FLASH_SR or FLASH_SSR.
3. Check that the write buffer is empty by checking the WDW bit in FLASH_SR or FLASH_SSR.
4. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
5. Set the PG bit in FLASH_CR or FLASH_SCR.
6. Perform the data write operation at the desired flash memory address, or in the OTP area. Only a double- word can be programmed and OTP can be only programmed in nonsecure access:
   - Write a first word at a double-word address boundary. The WDW bits in FLASH_SR and FLASH_SSR are set to indicate that more data can be written in the write buffer.
   - Write the second word in the same double-word.
7. The BSY bit gets set. WDW is reset automatically.
8. Wait until the BSY bit is cleared in FLASH_SR or FLASH_SSR. Software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.
9. If the EOP flag is set in FLASH_SR or FLASH_SSR (meaning that the programming operation has succeeded, and the EOPIE bit is set), it must be cleared by software.
10. Clear the PG bit in FLASH_CR or FLASH_SCR if there are no more programming requests.
11. Clear PG bit in FLASH_CR or FLASH_SCR if there is no more programming request.

Note: When the flash memory interface receives a good sequence (a double-word), programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when the PG bit is set, and disabled automatically when the PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR.

No option-byte modification nor erase request is allowed when the WDW bit is set.

Programming is possible only if the privileged and security attributes are respected (refer to Section 7.8).

If the user needs to program only one word, the double-word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the double-word to program.

The OTP data cannot be erased and are writable only once. If only one bit is at 0, the entire double word is not writable anymore, even with the value 0x0.

It is only possible to write one bank/cut after the other .

Flash burst programming (16 double-words)

The flash memory burst programming sequence is as follows:

1. Check that voltage range is set to range 1.
2. Check that no flash main memory operation is ongoing by checking the BSY bit in FLASH_SR or FLASH_SSR.
3. Check that the write buffer is empty by checking the WDW bit in FLASH_SR or FLASH_SSR.
4. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
5. Set the BWR and PG bits in FLASH_CR or FLASH_SCR.
6. Perform the data write operation at the desired flash memory address, or in the OTP area. Only 16 double-words can be programmed:
   - Write a first 32-bit word in an address aligned on a 16 double-word address (multiple of 0x80). The WDW bits in FLASH_SR and FLASH_SSR are set to indicate that more data can be written in the write buffer.
   - Write the 31 other 32-bit words consecutively.
7. The BSY bit gets set. WDW is reset automatically.
8. Wait until the BSY bit is cleared in FLASH_SR or FLASH_SSR. Software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.
9. If the EOP flag is set in FLASH_SR or FLASH_SSR (meaning that the programming operation has succeeded and the EOPIE bit is set), it has to be cleared by software.
10. Clear the BWR and PG bits in FLASH_CR or FLASH_SCR if there is no more programming request.

Note: When the flash memory interface receives a good sequence, programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when the PG bit is set, and disabled automatically when the PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR.

No option-byte modification nor erase request is allowed when the WDW bit is set.

Programming is possible only if the privileged and security attributes are respected (refer to Section 7.8).

7.3.8 Flash memory errors flags

Flash programming errors

Several types of errors can be detected during secure and nonsecure operations. In case of error, the flash memory operation (programming or erasing) is aborted.

The secure errors flags are only set during a secure operation and nonsecure flags are only set during a nonsecure operation.

All error flags linked to an operation error have the effect to flush the write buffer.

- **PROGERR**: secure/nonsecure programming error

  It is set when the word to program is pointing to an address:
  - Not previously erased
  - Already fully programmed to 0
  - Already partially programmed (contains 0 and 1) and the new value to program is not full zero
  - For OTP programming, when the address is already partially programmed (contains 0 and 1)
- **SIZERR**: secure/nonsecure size programming error

  Only 32-bit data can be written. SIZERR flag is set if a byte or a half-word is written.
- **PGAERR**: secure/nonsecure alignment programming error

  It is set when the first word to be programmed is not aligned with a double-word address, or the second word does not belong to the same double-word address.

  For burst programming, it is set when the first word to be programmed is not aligned on a 16 × double-word address or if the following word writes are not done at consecutive 32-bit addresses.
- **PGSERR**: programming sequence error

  It is set if one of the following conditions occurs during an erase, program, or option change programming operation:
  - A data is written when PG is cleared.
  - A program operation is requested during erase: PG is set while MER1 or MER2 or PER is set.
  - In the erase sequence, PG is set while STRT is already set.
  - In the erase sequence, if STRT is set while MER1 and MER2 and PER are cleared.
  - If page and mass erase are requested at the same time, STRT and PER are set while MER1 or MER2 is set.
  - If an operation is started while the write buffer is waiting for the next data, STRT or OPTSTRT is set while WDW is already set.
  - If STRT and OPTSTRT are set at the same time.
  - A nonsecure PGSERR is set if the non secure STRT bit is set by a secure access.
  - An erase, program, or option-byte programming (OPTSTRT) operation is launched while voltage range is set to range 2.
  - A secure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPERR, or PGSERR is already set due to a previous programming error.
  - A nonsecure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPERR, PGSERR, or OPTWERR is already set due to a previous programming error.
- **WRPERR**: write protection error
  - See *Table 55* to *Table 57* for all the conditions of WRPERR flag setting.

- **OPTWERR**: option-byte write error

  It is set if when user option bytes are modified with an invalid configuration. It is set when attempting:

  – To program an invalid secure watermark-based area (refer to *Table 42*)
  – To set or clear the TZEN option bit when RDP is not at correct level (refer to *Rules for modifying specific option bytes*)
  – To clear the BOOT_LOCK option bit when RDP is not at correct level (refer to *Rules for modifying specific option bytes*)
  – To modify SWAP_BANK option bit while BOOT_LOCK and TZEN are set
  – To modify ADD option bit (in FLASH_SBOOT0R) while BOOT_LOCK is set
  – To modify DUALBANK option bit while BOOT_LOCK and TZEN are set
  – To modify SECWM1Rx (resp. SECWM2Rx) in one of the following conditions:

    - while HDP1 (resp. HDP2) area access is disabled (HDP1_ACCDIS, resp. HDP2_ACCDIS, is different than 0xA3)

    - while HDP1 (resp. HDP2) extension area access is disabled (HDP1EXT_ACCDIS, resp. HDP2EXT_ACCDIS, is different than 0xA3).
  – To modify the option bytes, except the SWAP_BANK option bit, when RDP is set to two
  – To regress from RDP level 0.5 to RDP level 0
  – To modify OEM1KEYRx while RDP level is 0.5 or 1 and OEM1LOCK bit is set
  – To modify OEM2KEYRx while RDP level is 1 and OEM2LOCK bit is set
  – To regress from RDP level 1 to RDP level 0 while OEM1LOCK bit is set and a wrong OEM1KEY is shifted through JTAG or SWD
  – To regress from RDP level 1 to RDP level 0.5 while OEM2LOCK bit is set and a wrong OEM2KEY is shifted through JTAG or SWD
  – To program OEM1KEY with less than five zero.
  – To program OEM2KEY with less than five zero
  – To modify WRPxyR while its UNLOCK bit is cleared
  – To set the UNLOCK bit in the WRPxyR when RDP is not at correct level (refer to *Rules for modifying specific option bytes*)

If an error occurs during a secure or nonsecure program or erase operation, one of the following programming error flags is set:

- Nonsecure programming error flags: PROGERR, SIZERR, PGAERR, PGSERR, OPTWRERR, or WRPERR is set in FLASH_SR.
- If the nonsecure error interrupt enable bit ERRIE is set in FLASH_CR, an interrupt is generated and the operation error flag OPERR is set in FLASH_SR.
- Secure programming error flags: PROGERR, SIZERR, PGAERR, PGSERR, or WRPERR is set in FLASH_SSR.

  If the secure error interrupt enable bit ERRIE is set in FLASH_SCR, an interrupt is generated and the operation error flag OPERR is set in FLASH_SSR.

Note: If several successive errors are detected (for example, DMA transfer to the flash memory), the error flags cannot be cleared until the end of the successive write requests.

Any programming error flushes the write buffer.

7.3.9 Read-while-write (RWW)

The flash memory is divided into two banks allowing read-while-write operations. This feature allows a read operation to be performed from one bank while erase or program operation is performed to the other bank.

Note: Write-while-write operations are not allowed. As an example, it is not possible to perform an erase operation on one bank while programming the other one.

Read from bank 1 while page erasing in bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa).

Read from bank 1 while mass erasing bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa).

Read from bank 1 while programming bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a program operation on bank 2 (and vice versa).

Note: Due to the Cortex-M33 unified C-bus, user software must ensure to not stall C-bus with multiple consecutive writes. It is recommended to wait for the BSY flag to be cleared before programming the next double-word.

7.3.10 Power-down during flash programming or erase operation

The contents of the flash memory currently being accessed are not guaranteed if a power-down occurs during a flash memory program or erase operation.

7.3.11 Reset during flash programming or erase operation

The contents of the flash memory currently being accessed are not guaranteed if a reset occurs during a flash memory program or erase operation. The status of the flash memory can be recovered from FLASH_OPSR when a system reset occurs during a flash memory program or erase operation.

It is software responsibility to check the status of the flash memory and to take corrective actions. This must be done after each system reset before any other programming or erase operation is performed.

The table below describes the corrective action to be taken according to the status provided in the CODE_OP field of the FLASH_OPSR.

Table 39. Flash operation interrupted by a system reset

CODE_OP	Operation interrupted	Address	Bank	System flash	Corrective action
0x0	No operation	Reserved			None
0x1	Single write	ADDR_OP	BK_OP	SYSF_OP	Page erase and single write at same location
0x2	Burst Write	ADDR_OP	BK_OP	SYSF_OP	Page erase and burst write at same location
0x3	Page erase	ADDR_OP	BK_OP	Reserved	Erase same page

Table 39. Flash operation interrupted by a system reset (continued)

CODE_OP	Operation interrupted	Address	Bank	System flash	Corrective action
0x4	Bank erase	Reserved	BK_OP	Reserved	Erase same bank
0x5	Mass erase	Reserved			Mass erase
0x6	Option change	Reserved			Option change
0x7	Reserved				

Note: For single and burst write, it is mandatory to perform a page erase because the current flash memory locations may no longer be writable. Consequently, the remaining page content must be saved before page erase and restored afterwards.

For OTP write, it is not possible to perform a page erase. The OTP double-word is lost.

For burst write, ADDR_OP gives the first address of burst. The user must restart the same burst operation. For page erase, ADDR_OP gives the first address of erased page.

7.4 FLASH option bytes

7.4.1 Option-byte description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog can be selected in hardware or software mode (refer to *Section 7.4.2*). The user option bytes are accessible through the flash memory registers.

Table 40 describes the organization of all user option bytes available in the flash memory registers.

Table 40. User option-byte organization mapping

7.4.2 Option-byte programming

Unlocking option control register

After reset, the options related to the operation bits OPTSTRT and OBL_LAUNCH in FLASH_CR, are write-protected. To run any operation on the option-byte page, the option lock bit OPTLOCK in FLASH_CR must be cleared.

The option-byte programming (OPTSTRT) can only be launched in range 1.

The following sequence is used to unlock OPTSTRT and OBL_LAUNCH bits:

1. Unlock the FLASH_CR register with the LOCK clearing sequence (refer to *Unlock the secure/nonsecure flash control registers*).
2. Write KEY1 = 0x08192A3B in FLASH_OPTKEYR.
3. Write KEY2 = 0x4C5D6E7F in FLASH_OPTKEYRR.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If the LOCK bit in FLASH_CR is set by software, OPTLOCK is automatically set too.

Option-byte modification sequence

To modify the user options value, follow the procedure below:

1. Check that voltage range is set to range 1.
2. Check that no flash memory operation is ongoing by checking the BSY bit. Check that the write buffer is empty by checking the WDW bit in FLASH_SR.
3. Clear OPTLOCK option lock bit with the clearing sequence described above.
4. Clear all nonsecure error flags due to a previous operation
5. Write the desired options value in the options registers.
6. Set the option start bit OPTSTRT in FLASH_CR.
7. Wait for the BSY bit to be cleared.
8. Set the OBL_LAUNCH option bit to start option-byte loading.

Note: If the OPTWERR or PGSERR error bit is set, the old option-byte values are kept.

Option-byte loading

After the BSY bit is cleared, all new options are updated into the flash memory but they are not applied to the system. They affect the system when they are loaded. Option-byte loading (OBL) is performed in two cases:

- When OBL_LAUNCH bit is set in FLASH_CR
- After a power reset (BOR reset or exit from Standby/Shutdown modes)

On system reset rising, internal option registers are copied into option registers. These registers are also used to modify the option bytes. If these registers are not modified by the user, they reflect the option state of the system.

Rules for modifying specific option bytes

Some of the option-bytes must respect specific rules before being updated with new values. These option bytes, as well as the associated constraints, are described below:

- TZEN option bit
  - TZEN can only be set on RDP level 0.
  - Deactivation of TZEN is only possible when RDP is changing from level 1 to 0.
- BOOT_LOCK option bit
  - BOOT_LOCK has only effect when TZEN is set.
  - BOOT_LOCK can be set without any constraint.
  - Deactivation of BOOT_LOCK is only possible when RDP is level 0.
- SWAP_BANK option bit
  - It cannot be modified when BOOT_LOCK and TZEN option bits are set.
- ADD (in FLASH_SBOOT0R) option bytes
  - It cannot be modified when BOOT_LOCK option bit is set.
- DUALBANK option bit
  - It cannot be modified when BOOT_LOCK and TZEN option bits are set.

- SECWMxRy option bits
  - It is not possible to modify secure (SECWMx_STRT[6:0] and SECWMx_END[6:0] option bits), and HDP (HDPx_END[6:0] and HDPxEN[7:0] option bits) area in bank x when the HDP area access is disabled (HDPx_ACCDIS ≠ 0xA3), or when the HDP extension area access is disabled (HDPxEXT_ACCDIS ≠ 0xA3).
- RDP option bits
  - Refer to *Device life cycle managed by readout protection (RDP) transitions*.
- WRPxyR option bits
  - These bits cannot be modified when their UNLOCK bit is cleared.
- UNLOCK option bits
  - These bits can be set only when regressing from RDP level 1 to level 0.

If the user option modification tries to set or modify one of the listed option bytes without following their associated rules, the option-byte modification is discarded and the OPTWERR error flag is set.

7.5 FLASH TrustZone security and privilege protections

7.5.1 TrustZone security protection

The global TrustZone system security is activated by setting the TZEN option bit in FLASH_OPTR. When TrustZone is active (TZEN = 1), the following additional security features are available:

- Secure watermark-based user options bytes defining secure and HDP areas
- Secure HDP extension areas
- Secure or nonsecure block-based areas can be configured on-the-fly after reset. This is a volatile secure area.
- An additional RDP protection: RDP level 0.5
- Erase or program operation can be performed in secure or nonsecure mode with associated configuration bit.

When the TrustZone is disabled (TZEN = 0), the above features are deactivated, and all secure registers are RAZ/WI.

Activate TrustZone security

When the TrustZone is activated (TZEN modified from 0 to 1), the secure watermark-based user option bytes are set to default secure state: all flash memory is secure, and no HDP area, as shown in the table below.

Table 41. Default secure option bytes after TZEN activation

Secure watermark option-byte values after OBL when TZEN is activated (from 0 to 1)	Security attribute
SECWMx_STRT = 0 and SECWMx_END = 0x7F	All flash memory secure
HDPxEN = 0xB4 and HDPx_END = 0	No secure HDP area

Illegal access generation

A nonsecure access to a secure flash memory area is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in GTZC1_TZIC_IER2.

A nonsecure access to a secure FLASH register generates an illegal access event. An illegal access interrupt is generated if FLASH_REGIE illegal access interrupt is enabled in GTZC1_TZIC_IER2.

Deactivate TrustZone security

Deactivation of TZEN (from 1 to 0) is only possible when the RDP is changing from level 1 to level 0.

When the TrustZone is deactivated (TZEN modified from 1 to 0) after option-byte loading, the following security features are deactivated:

- Watermark-based secure area (refer to *Section 7.5.2*)
- Block-based secure area (refer to *Section 7.5.5*)
- RDP level 0.5 (refer to *Section 7.6.2*)
- Secure interrupts (refer to *Section 7.9*)
- All secure registers are RAZ/WI.

7.5.2 Watermark-based secure flash memory area protection

When TrustZone security is active (TZEN = 1), a part of the flash memory can be protected against nonsecure read and write accesses. Up to two different nonvolatile secure areas can be defined by option bytes, and can be read or written by a secure access only: one area per bank can be selected with a page granularity.

The secure areas are defined by a start-page offset and end-page offset using SECWMx_STRT and SECWMx_END (x = 1,2 for area 1 and area 2) option bytes. These offsets are defined in secure watermark registers address registers FLASH_SECWM1R1 and FLASH_SECWM1R2.

SECWMx_STRT and SECWMx_END option bytes can only be modified by secure firmware when the HDPx_ACCDIS and HDPxEXT_ACCDIS value is reseted (0xA3).
If HDPx_ACCDIS or HDPxEXT_ACCDIS is different than reset value (0xA3), SECWMx_STRT and SECWMx_END cannot be modified until next system reset.

Table 42. Secure watermark-based area

Secure watermark option-byte values (x = 1,2)	Secure watermark protection area
SECWMx_STRT > SECWMx_END	No secure area
SECWMx_STRT = SECWMx_END	One page defined by SECWMx_STRT is secure watermark-based protected
SECWMx_STRT < SECWMx_END	The area between SECWMx_STRT and SECWMx_END is secure watermark-based protected.

Caution: Switching a flash memory area from secure to nonsecure does not erase its content. User secure software must perform the needed operation to erase the secure area before

switching an area to nonsecure attribute, whenever is needed. It is also recommended to flush the instruction cache.

7.5.3 Secure hide protection (HDP)

The secure HDP area is part of the flash memory watermark-based secure area. Access to the hide protection area can be denied by setting HDPx_ACCDIS or HDPxEXT_ACCDIS (x = 1,2 for area 1 and area 2) to a value other than 0xA3 in FLASH_SECHDPCR.

When the HDPx_ACCDIS or HDPxEXT_ACCDIS bit is activated (value ≠ 0xA3), instruction fetch, data read, write and erase operations on this hide protection area are denied.
For example, software code in the secure FLASH hide protected area can be executed only once, and deny any further access to this area until next system reset. The HDPx_ACCDIS or HDPxEXT_ACCDIS bits can be reseted (HDPx_ACCDIS = 0xA3 or HDPxEXT_ACCDIS = 0xA3) only by a system reset.

When a secure HDPx area is defined (HDPxEN = 0xB4 and SECWMx_STRT ≤ HDPx_END ≤ SECWMx_END), it is forbidden to fetch outside the HDPx area until the HDPx area is closed (HDPx_ACCDIS ≠ 0xA3).

The HDP area protection are summarized in *Table 56*.

Note: It is software responsibility to take any appropriate action to protect the HDP code before deactivating the HDPxEN bits (HDPxEN = 0xB4), such as erasing the HDP area and flushing the instruction cache.

One nonvolatile secure hide protection (HDP) area per bank can be defined with a page granularity.

The secure HDP area is enabled by the HDPxEN (x = 1,2 for area 1 and area 2). When the HDPxEN bit is deactivated (HDPxEN = 0xB4), there is no HDP area. The HDPxEN bits can be modified on-the-fly by secure firmware if the HDPx_ACCDIS is set to reset value (HDPx_ACCDIS = 0xA3). If HDPx_ACCDIS is different than reset value, the HDPxEN bits and secure watermark configuration cannot be modified until next system reset.

The secure HDP area size is defined by the end-page offset using the HDPx_END option bytes, while the start- page offset is already defined by SECWMx_STRT option bytes.These offsets are defined in secure watermark registers address registers (FLASH_SECWM1R1, FLASH_SECWM1R2, FLASH_SECWM2R1, and FLASH_SECWM2R2).

For example, to protect by HDP from the address 0x0C00 4000 (included) to the address 0x0C00 5FFF (included):

- If banks are not swapped, the option-byte registers must be programmed with:
  - SECWM1_STRT = 0x4
  - HDP1_END = 0x5
- If the two banks are swapped, the protection must apply to bank 2, and the option-byte registers must be programmed with:
  - SECWM2_STRT = 0x4
  - HDP2_END = 0x5

Note: For more details on the bank swapping mechanism, refer to Section 7.5.9.

If an invalid secure HDP area is defined as described in the table below, the OPTWERR flag error is set, and option-byte modification is discarded.

Table 43. Secure hide protection

HDPx watermark option-byte values (x = 1,2)		Hide protection area
HDPxEN = 0xB4	-	No secure HDP area
HDPxEN ≠ 0xB4	SECWMx_STRT ≤ HDPx_END ≤ SECWMx_END	The area between SECWMx_STRT and HDPx_END is secure HDP protected.
	Others	Invalid secure area. Hide protection area is defined outside the secure area.

The table below summarizes the possible secure and HPD protection area configurations.

Table 44. Secure and HDP protections

Secure and HDP watermark option-byte values		Protections area
HDPxEN	**Option bytes**	
x	SECWMx_STRT > SECWMx_END	No secure area
0xB4	SECWMx_STRT ≤ SECWMx_END	No secure HDP area Secure between SECWMx_STRT and SECWMx_END If SECWMx_STRT = SECWMx_END, one page defined by SECWMx_STRT is secure protected.
≠ 0xB4	SECWMx_STRT ≤ HDPx_END ≤ SECWMx_END	The area between SECWMx_STRT and HDPx_END is secure HDP protected. If SECWMx_STRT = HDPx_END, one page defined by HDPx_END is secure HDP protected.
	Others	Invalid secure area HDP area is defined outside the secure area.

7.5.4 Secure hide protection extension (HDP extension)

The secure HDPx (x = 1,2 for area 1 and area 2) area can be extended using HDPx_EXT values in FLASH_SECHDPCR. HDPx_EXT indicates the number of pages added to the HDP area.

The HDPx extension is only composed by the secure HDPx_EXT pages which belong to the flash memory watermark-based secure area. Any pages outside the watermark-based secure area are not part of the HDPx extension area. It means the end page offset of the HDPx extension area cannot be greater than SECWMx_END.

The start page offset of the HDPx extension area depends on the presence of an HDPx area. If there is an HDPx area, the HDPx extension area starts from HDPx_END + 1. Otherwise, it starts from SECWMx_STRT.

Note: If there is no watermark-based secure area, there is no HDP extension. An HDP extension area can be defined even if there is no valid HDP area

HDP extension area access

Access to the HDPx extension area can be denied thanks to HDPxEXT_ACCDIS bits in FLASH_SECHDPCR.

- When HDPxEXT_ACCDIS value is set to the reset value (0xA3), access to the HDPx extension is granted. There is no write access restrictions to HDPx_EXT and HDPxEXT_ACCDIS bits.
- When HDPxEXT_ACCDIS value is set to 0x5C, any operations (instruction fetch, data read, write and erase) to the HDPx extension or HDPx is denied until next system reset. Moreover, HDPx extension area size can only be incremented.

  There are some write access restrictions on HDPx_EXT and HPxEXT_ACCDIS bits:
  - HDPx_EXT can only be incremented.
  - HDPxEXT_ACCDIS cannot be set to 0xA3.
- When HDPxEXT_ACCDIS value is set to a value different than 0xA3 and 0x5C, any operations (instruction fetch, data read, write and erase) to the HDPx extension or HDPx is denied until next system reset. Moreover HDPx extension area size cannot be modified until next system reset.

  There are some write access restrictions on HDPx_EXT and HPxEXT_ACCDIS bits:
  - Write access to HDPx_EXT bits are ignored.
  - Write access to HDPxEXT_ACCDIS bits are ignored

Table 45. Write access register to HDPx_EXT and HDPxEXT_ACCDIS

Current HDPxEXT_ACCDIS value	Write access to		Operation (fetch, read, write, erase) in HDPx extended area	Operation (fetch, read, write, erase) in HDPx area
	HDPxEXT_ACCDIS	HDPx_EXT		
0xA3 (reset value)	OK	OK	Allowed	Depends on HDPx_ACCDIS value
0x5C	OK if new value different than 0xA3. Otherwise, write access is ignored	OK if new value greater than current value. Otherwise, write access is ignored.	Denied	Denied
Others	Write ignored	Write ignored		

When the HDPx extension is enabled (HDPxEXT_ACCDIS ≠ 0xA3), the HDPxEN bits and secure watermark configuration cannot be modified until next system reset (refer to *Rules for modifying specific option bytes*).

One volatile secure hide protection extension (HDP extension) area per bank can be defined with a page granularity.

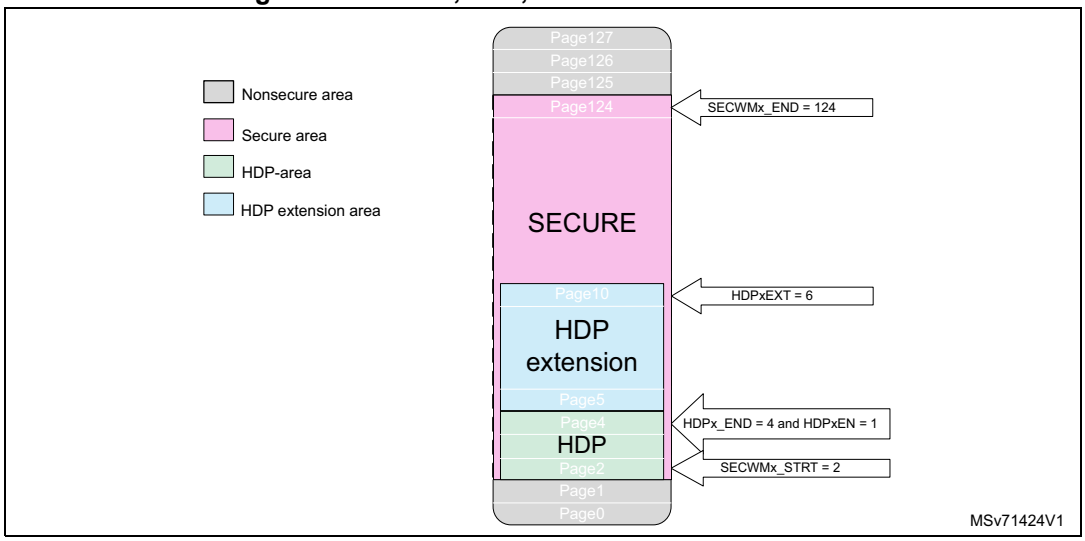
When a HDPx extension area is defined and it is still open (HDPxEXT_ACCDIS = 0xA3) and there is not any open HDP area, it is forbidden to fetch outside the HDPx extended area until it is closed (HDPxEXT_ACCDIS ≠ 0xA3). The HDP and HDP extension area protection are summarized in *Table 56*.

The table below summarizes the possible HDP extension area configurations.

Table 46. HDP extension protections

Secure and HDP watermark option-byte values		HDP extension area
HDPxEN	**Option bytes**	
≠ 0xB4	HDPx_END < SECWMx_END	The secure HDPx extension is composed by the following pages: HDPx_END +1 ≤ pages ≤ min (HDPx_END + HDPx_EXT , SECWMx_END)
≠ 0xB4	HDPx_END = SECWMx_END	No secure HDPx extension area
0xB4	-	The secure HDPx extension is composed by the following pages: SECWMx_STRT ≤ pages ≤ min (SECWMx_STRT - 1 + HDPx_EXT, SECWMx_END)

For example:



SECWM1_STRT = 0x2 SECWM1_END = 0x7C

HDP1_END = 0x4 and HDP1EN ≠ 0xB4

HDP1_EXT = 0x6

Pages from 0x2 to 0x4 (included) are protected by HDP and the pages from 0x5 to 0xA are protected by the HDP extension. This is illustrated by the figure below.

Figure 16. Secure, HDP, and HDP extension areas

Other examples:

- SECWM1_STRT = 0x6 and SECWM1_END = 0x7C

  HDP1EN = 0xB4

  HDP1_EXT = 0x6

  There is no valid HDP area. Pages from 0x6 to 0x7C are secure. The pages from 0x6 to 0xB are protected by the HDP extension.

- SECWM1_STRT = 0x6 and SECWM1_END = 0x10
  HDP1_END = 0xB and HPD1EN ≠ 0xB4
  HDP1_EXT = 0x9
  Pages from 0x6 to 0xB (included) are protected by HDP. The pages from 0xC to 0x10 are protected by the HDP extension.

7.5.5 Block-based secure flash memory area protection

Any page can be programmed on-the-fly as secure or nonsecure using the block-based configuration registers. FLASH_SECBB1Rx (resp. FLASH_SECBB2Rx) are used to configure the security attribute for pages in bank 1 (resp. bank 2).

When the page security attribute (bit i in SECBByRx) is set, the security attribute is the same as the secure watermark-based area. The secure page is only accessible by a secure access.

If the SECBByRx[i] bit is set or reset for a page already included in a secure watermark-based area, the page keeps the watermark-based protection security attributes.

To modify a block-based page security attribution, the following actions are recommended:

- Check that no flash memory operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in SECBByRx.

Caution: Switching a page or memory block from secure to nonsecure does not erase the content of the associated block. User secure software must perform the following needed operations before switching a block to nonsecure attribute:

- Erase page content,
- Invalidate the instruction cache.

Note: For SECBByRx bit i access control, refer to Table 63.

7.5.6 Flash security attribute state

The flash memory is secure when at least one secure area is defined either by watermark-based option bytes or block-based security registers.

It is possible to override the flash security state using the INV bit in FLASH_SCR.

FLASHEN and FLASHSMEN bits security attributes in the RCC follow the flash memory security attribute. It is possible to override the flash memory security attribute in the RCC using the INV bit in FLASH_SCR. A secure firmware setting this INV bit allows a nonsecure firmware to disable the flash memory clock when the flash memory is in power down or when the MCU enters low-power modes.

Table 47. Flash security state

Secure area	INV bit	Flash security state
None	0	Nonsecure
	1	Secure
Yes	0	Secure
	1	Nonsecure

7.5.7 Block-based privileged flash memory area protection

Any page can be programmed on-the-fly as privileged or unprivileged using the block-based configuration registers. FLASH_PRIVBB1Rx (resp. FLASH_PRIVBB2Rx) are used to configure the privilege attribute for pages in bank 1 (resp. bank 2).

When the page privilege attribute (bit i in PRIVBByRx) is set, the page is only accessible by a privileged access. An unprivileged page is accessible by a privileged or unprivileged access.

To modify a block-based privilege attribution, the following actions are recommended:

- Check that no flash operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in PRIVBByRx.

Caution: Switching a page or memory block from privileged to unprivileged does not erase the content of the associated block.

Note: For PRIVBByRx bit i access control, refer to Table 64 and Table 65.

7.5.8 Flash memory register privileged and unprivileged modes

The flash memory registers can be read and written by privileged and unprivileged accesses, depending on the SPRIV and PRIV bits in FLASH_PRIVCFGR, with the following rules:

- When the SPRIV (resp. PRIV) bit is reset, all secure (resp. nonsecure) flash memory registers can be read and written by both privileged or unprivileged access.
- When the SPRIV (resp. PRIV) bit is set, all secure (resp. nonsecure) flash memory registers can be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

Table 60 summarizes the flash memory registers access control.

7.5.9 Flash memory bank attributes in case of bank swap

The SWAP_BANK option bit modifies the address of each bank in the memory map. When SWAP_BANK is reset, the flash memory bank 1 is at the lower address range. When SWAP_BANK is set, the flash memory bank 1 is at the higher address range.

Flash memory bank attributes follow their bank so there is no need to modify the following registers when swapping banks:

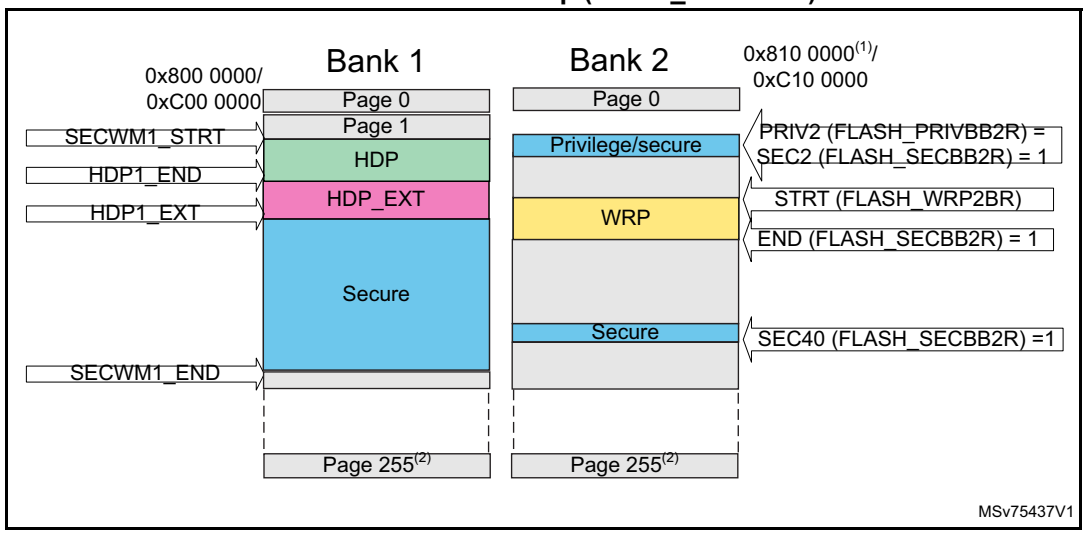
- FLASH secure watermark y register x FLASH_SECWMyRx
- FLASH write protection x area y FLASH_WRPxyR (refer to *Section 7.6.1*)
- FLASH secure block based bank y register x FLASH_SECBByRx
- FLASH privilege block based bank y register x FLASH_PRIVBByRx
- PDREQx bits in FLASH_ACR
- PDx bits in FLASH_SR

Note: The BK_ECC bit in FLASH_ECCCORR always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.

The BK_OP bit in FLASH_ECCDETR always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.

The figures below show how security attributes and protections behave in case of bank swap.

Figure 17. Flash memory security attributes and protections in case of no bank swap (SWAP_BANK = 0)



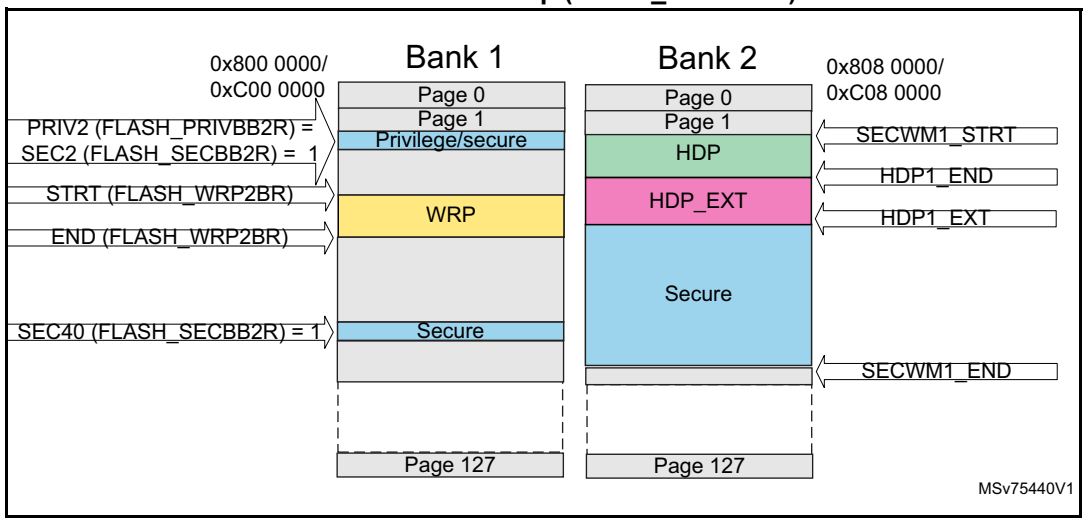


Figure 18. Flash memory security attributes and protections in case of bank swap (SWAP_BANK = 1)

7.6 FLASH memory protection

The flash memory interface implements the following protection mechanisms:

- Write protection (WRP)
- Readout protection (RDP)
- Additional secure protections when TrustZone is active (refer to *Section 7.5*)
  - Up to two secure watermark-based nonvolatile areas
  - Up to two secure hide protection areas
  - Secure block-based volatile areas with page granularity
- Privileged block-based volatile areas with page granularity (refer to *Section 7.5.7*)

7.6.1 Write protection (WRP)

The user area in the flash memory can be protected against unwanted write operations. Two write-protected (WRP) areas can be defined in each bank, with page granularity.

Each area is defined by a start page offset and an end page offset related to the physical flash bank base address. These offsets are defined in the WRP address registers: FLASH_WRP1AR , FLASH_WRP1BR , FLASH_WRP2AR, and FLASH_WRP2BR.

The bank "x" WRP "y" area (x = 1,2 and y = A,B) is defined as follows:

- From the address: bank "x" base address + [FLASH_WRPxyR[STRT] × 0x1000] (included)
- To the address: bank "x" base address + [(FLASH_WRPxyR[END]+1) × 0x1000] (excluded)

For example, to protect by WRP from the address 0x0806 2000 (included) to the address 0x0807 3FFF (included):

- If the banks are not swapped, FLASH_WRP1AR must be programmed with:
  - STRT = 0x62
  - END = 0x73

  STRT and END in FLASH_WRP1BR can be used instead (area "B" in bank 1).
- If the two banks are swapped, the protection must apply to bank 2, and FLASH_WRP2AR must be programmed with:
  - STRT = 0x62
  - END = 0x73

  STRT and END in FLASH_WRP2BR can be used instead (area "B" in bank 2).

Note: For more details on the bank swapping mechanism, refer to Section 7.5.9.

When WRP is active, protected flash memory pages cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the flash memory is attempted, the secure or nonsecure write protection error flag (WRPERR) is set in FLASH_SR or FLASH_SSR. This flag is also set for any write access to the following:

- System flash memory
- OTP area

Note: When the memory readout protection level 1 is selected (RDP level = 1), it is not possible to program or erase the flash memory (secure or nonsecure) if the CPU debug features are

connected (JTAG or single wire) or boot code is being executed from RAM or system flash memory, even if WRP is not activated.

When the memory readout protection level 0.5 is selected (RDP level = 0.5), it is not possible to program or erase the flash secure memory if the CPU debug features are connected (JTAG or single wire), even if WRP is not activated.

To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in the flash control register.

Table 48. WRP protection

WRP registers values (x = 1/2 y = A/B)	WRP area
FLASH_WRPxy[STRT] = FLASH_WRPxy[END]	Page WRPxy is protected.
FLASH_WRPxy[STRT] > FLASH_WRPxy[END]	No WRP area
FLASH_WRPxy[STRT] < FLASH_WRPxy[END]	The pages from FLASH_WRPxy[STRT] to FLASH_WRPxy[END] are protected.

Write protection lock

Each WRP area can be independently locked by writing 0 to the UNLOCK bit in FLASH_WRP1AR, FLASH_WRP1BR, FLASH_WRP2AR, or FLASH_WRP2BR. Once a WRP area is locked, it is not possible to modify its settings. In order to unlock a WRP area, a regression to RDP level 0 must be launched.

In order to make the WRP area immutable and act as a ROM, the following actions are needed:

- If RDP level is 0, 0.5 or 1, provision a OEM1KEY in order to prevent a regression to RDP level 0 for users not knowing the key.
- If RDP level is 2, either provision a OEM1KEY (refer to first bullet) or do not provision a OEM2KEY (preventing regression from level 2 to level 1).

For more information on RDP regressions, refer to *Device life cycle managed by readout protection (RDP) transitions*.

7.6.2 Readout protection (RDP)

The readout protection protects the flash main memory, the option bytes, the backup registers, and the SRAMs. In order to reach the best protection level, it is recommended to activate TrustZone, and to set the RDP level 2 with password authentication regression enabled (refer to *Readout protection levels when TrustZone is enabled*).

Readout protection levels when TrustZone is disabled

There are three levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2).

The flash memory is protected according to the RDP option-byte value shown in the table below.

Table 49. Flash memory readout protection status (TZEN = 0)

RDP byte value	Readout protection level
0xAA	Level 0
Any value except 0xAA or 0xCC	Level 1
0xCC	Level 2

- **Level 0**: no protection

  Read, program and erase operations into the flash main memory area are possible. Option bytes, SRAMs, and backup registers are also accessible by all operations.
- **Level 1**: readout protection

  When the readout protection level 1 is set:
  - **User mode**: code executing in user mode (boot flash) can access the flash main memory, option bytes, SRAMs, and backup registers with all operations (read, erase, program).
  - **Debug, boot RAM, and bootloader modes**: in debug mode or when the microcontroller boots from RAM or system memory, the flash main memory, the backup registers, and the SRAM2 are totally inaccessible. Any read or write access to the flash main memory generates a bus error and a hard fault interrupt.
- **Level 2:** no debug

  When the readout protection level 2 is set:
  - The protection level 1 is guaranteed.
  - All debug features are disabled:

    - if OEM2 key has not been provided, JTAG and SWD are definitively disabled.

    - if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST, and DBGMCU_DBG_AUTH_DEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.
  - The boot from SRAM (boot RAM mode) and the boot from system memory (bootloader mode) are no longer available.
  - Only boot from main flash memory is possible; all operations are allowed on the flash main memory. Read, erase and program accesses to the flash memory and SRAMs from user code are allowed.
  - Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to *OEM2 RDP lock mechanism*).

Note: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).

Table 50. Access status versus protection level and execution mode when TZEN = 0

Area	RDP level	User execution (boot from flash)			Debug/boot from RAM/ bootloader(1)		
		Read	Write	Erase	Read	Write	Erase
Flash main memory	1	Yes	Yes	Yes	No	No	No(2)
	2	Yes	Yes	Yes	N/A	N/A	N/A
System memory(3)	1	Yes	No	No	Yes	No	No
	2	Yes	No	No	N/A	N/A	N/A
Option bytes(4)	1	Yes	Yes(2)	N/A	Yes	Yes	N/A
	2	Yes	No(5)	N/A	N/A	N/A	N/A
OTP	1	Yes	Yes(6)	N/A	Yes	Yes(6)	N/A
	2	Yes	Yes(6)	N/A	N/A	N/A	N/A
Backup registers	1	Yes	Yes	N/A	No	No	N/A(7)
	2	Yes	Yes	N/A	N/A	N/A	N/A
SRAM2	1	Yes	Yes	N/A	No	No	N/A(8)
	2	Yes	Yes	N/A	N/A	N/A	N/A

1. When the protection level 2 is active, the debug port, the boot from RAM and the boot from system memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
4. Option bytes are only accessible through the flash registers interface and OPTSTRT bit.
5. SWAP_BANK option bit can be modified.
6. OTP can only be written once.
7. The backup registers are erased when RDP changes from level 1 to level 0.
8. All SRAMs are erased when RDP changes from level 1 to level 0. .

Readout protection levels when TrustZone is enabled

There are four levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2). The flash memory is protected according to the RDP option-byte value shown in the table below.

Table 51. Flash memory readout protection status (TZEN = 1)

RDP byte value	Readout protection level
0xAA	Level 0
0x55	Level 0.5
Any value except 0xAA or 0x55 or 0xCC	Level 1
0xCC	Level 2

- **Level 0**: no protection

  Read, program and erase operations into the flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.

  – RSS mode: when booting from RSS, the debug access is disabled while executing RSS code.

- **Level 0.5**: nonsecure debug only

  All read and write operations (if no write protection is set) from/to the nonsecure flash memory are possible. The debug access to secure area is prohibited. Debug access to nonsecure area remains possible.

  – **User mode**: code executing in user mode (boot flash) can access the flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).

  – **Nonsecure debug mode**: nonsecure debug is possible when the CPU is in nonsecure state. The secure flash memory, secure backup registers, and SRAMs are inaccessible. The nonsecure flash memory, nonsecure backup registers, and nonsecure SRAMs remain accessible for debug purpose.

  – **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.

  – **Boot RAM mode**: boot from SRAM is not possible.

- **Level 1**: readout protection

  When the readout protection level 1 is set:

  – **User mode**: code executing in user mode (boot flash) can access the flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).

  – **Nonsecure debug mode**: nonsecure debug is possible when the CPU is in nonsecure state. However, an intrusion is detected in case of debug access: the flash main memory, backup registers, and the SRAM2 are totally inaccessible. Any read or write access to the flash main memory generates a bus error and a hard fault interrupt.

  – **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.

  – **Boot RAM mod**e: boot from SRAM is not possible.

- **Level 2**: no debug

  When the readout protection level 2 is set:

  – The protection level 1 is guaranteed.

  – All debug features are disabled

  -if OEM2 key has not been provided, JTAG and SWD are definitively disabled.

  – -if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST, and DBGMCU_DBG_AUTH_DEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.

  – The boot from SRAM (boot RAM mode) and the boot from system memory (boot loader mode) are no longer available.

  – Boot from RSS is possible.

– When booting from main flash or RSS, all operations are allowed on the flash main memory. Read, erase and program accesses to flash memory and SRAMs from user code are allowed.
– Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to *OEM2 RDP lock mechanism*).

Note: The debug feature is also disabled under reset.

*STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (*refer to *OEM2 RDP lock mechanism*).

Table 52. Access status versus protection level and execution modes when TZEN = 1

Area	RDP level	User execution (boot from flash)			Debug/bootloader(1)		
		Read	Write	Erase	Read	Write	Erase
Flash main memory	0.5	Yes	Yes	Yes	Yes(2)	Yes(2)	Yes(2)
	1	Yes	Yes	Yes	No	No	No(5)
	2	Yes	Yes	Yes	N/A	N/A	N/A
System memory(3)	0.5	Yes	No	No	Yes	No	No
	1	Yes	No	No	Yes	No	No
	2	Yes	No	No	N/A	N/A	N/A
Option bytes(4)	0.5	Yes	Yes(5)	N/A	Yes	Yes(5)	N/A
	1	Yes	Yes(5)	N/A	Yes	Yes(5)	N/A
	2	Yes	No(6)	N/A	N/A	N/A	N/A
OTP	0.5	Yes	Yes(7)	N/A	Yes	Yes(7)	N/A
	1	Yes	Yes(7)	N/A	Yes	Yes(7)	N/A
	2	Yes	Yes(7)	N/A	N/A	N/A	N/A
Backup registers	0.5	Yes	Yes	N/A	Yes(2)	Yes(2)	N/A(8)
	1	Yes	Yes	N/A	No	No	N/A(8)
	2	Yes	Yes	N/A	N/A	N/A	N/A
SRAM2	0.5	Yes	Yes	N/A	Yes(2)	Yes(2)	N/A(9)
	1	Yes	Yes	N/A	No	No	N/A(9)
	2	Yes	Yes	N/A	N/A	N/A	N/A

1. When the protection level 2 is active, the debug port and the bootloader mode are disabled.
2. Depends on TrustZone security access rights.
3. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
4. Option bytes are only accessible through the flash registers interface and OPTSTRT bit.
5. The flash main memory is erased when the RDP option byte regresses from level 1 to level 0.
6. SWAP_BANK option bit can be modified.
7. OTP can only be written once.

8. The backup registers are erased when RDP changes from level 1 to level 0 and when RDP changes from level 1 to level 0.5.
9. All SRAMs are erased when RDP changes from level 1 to level 0 and when RDP changes from level 1 to level 0.5.

Device life cycle managed by readout protection (RDP) transitions

It is easy to move from level 0 or level 0.5 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 0.5 or from level 1. Once in level 2, it is no longer possible to modify the readout protection level unless an OEM2 key is provisioned (refer to *OEM2 RDP lock mechanism*).

When the RDP is reprogrammed to the value 0xAA to move from level 1 to level 0, a mass erase of the flash main memory and all SRAMs is performed. Backup registers, ICACHE, and PKA SRAM are also erased. The OTP area is not erased.

At RDP level 0.5, it is not possible to request RDP level 0. Instead, a RDP increase to level 1 followed by a RDP regression to level 0 is required.

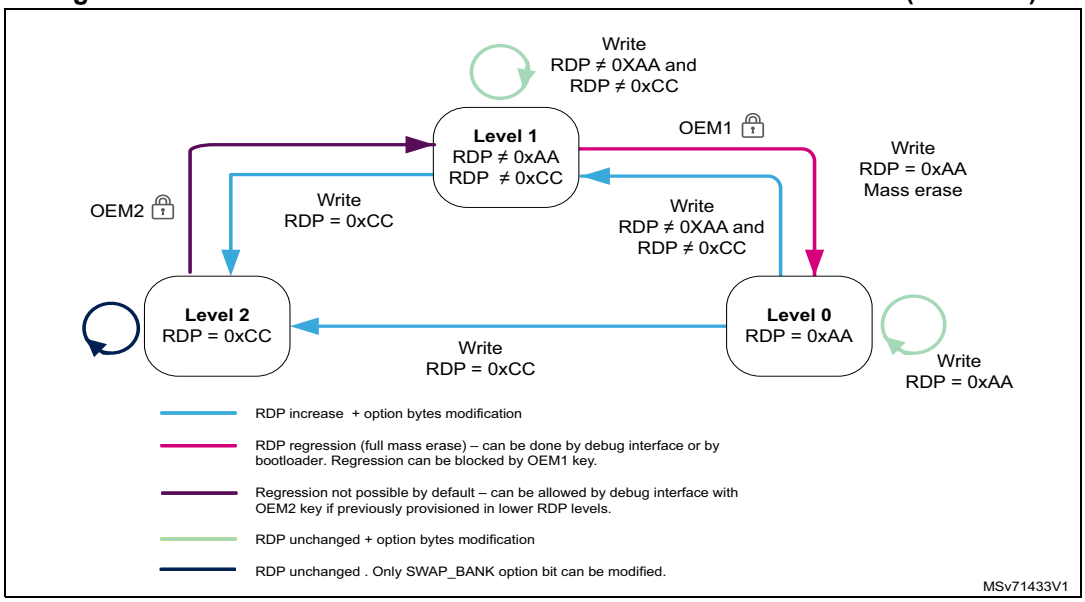
When the RDP is programmed to the value 0x55 to move from level 1 to level 0.5, a partial mass erase of the flash main memory is performed. Only nonsecure watermark-based areas are erased (even if it is defined as secure by block-based). Backup registers, ICACHE, PKA SRAM, and all SRAMs are mass erased. The OTP area is not erased. The RDP level 0.5 and partial nonsecure erase are only available when TrustZone is active.

Note: Full mass erase is performed only when level 1 is active and level 0 requested. When the protection level is increased (0 to 0.5, 0 to 1, 0.5 to 1, 1 to 2, 0 to 2 or 0.5 to 2), there is no mass erase.

To validate the readout protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in FLASH_CR.

Before launching a RDP regression, the software must invalidate the ICACHE and wait for the BUSYF bit to be cleared.

Figure 19. RDP level transition scheme when TrustZone is disabled (TZEN = 0)



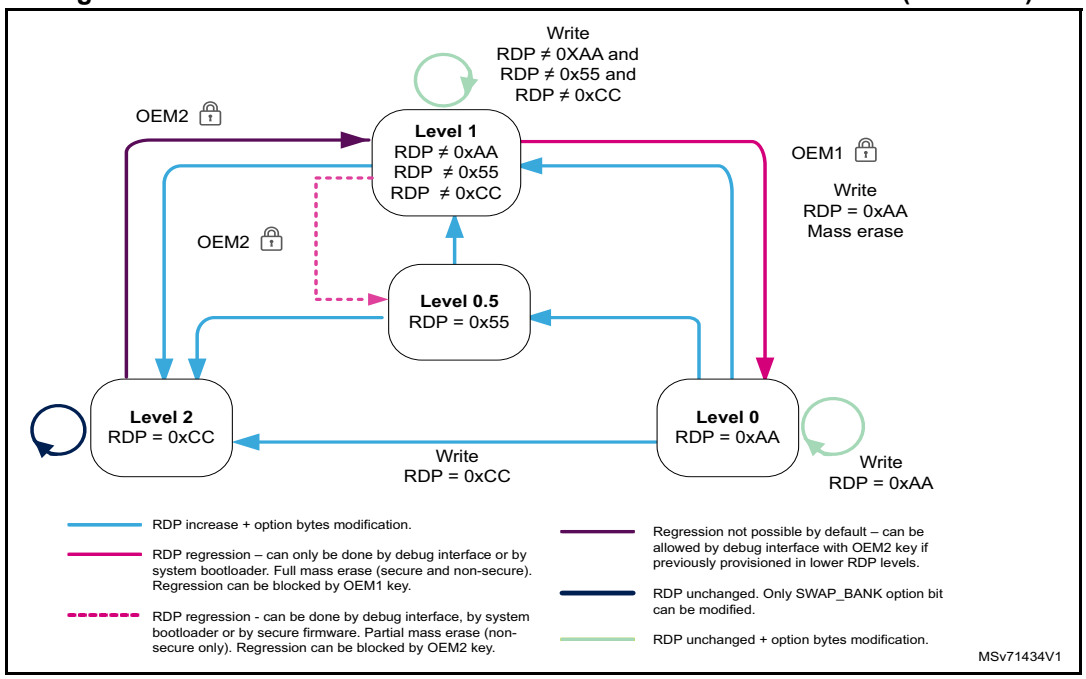


Figure 20. RDP level transition scheme when TrustZone is enabled (TZEN = 1)

OEM1/OEM2 lock activation

Two 128-bit keys (OEM1KEY and OEM2KEY) can be defined in order to lock the RDP regression. Each 128-bit key is coded on four registers:

- OEM1KEY coded on FLASH_OEM1KEYRx (x = 1 to 4)
- OEM2KEY coded on FLASH_OEM2KEYRx (x = 1 to 4).

OEM1KEY and OEM2KEY cannot be read through these registers but there are two 8-bit CRC (OEM1KEYCRC and OEM2KEYCRC), which can be used as a public key information.

Any read access to OEM1KEY and OEM2KEY returns zero.

OEM1KEY can be modified:

- In readout protection level 0
- In readout protection level 0.5 or 1 if OEM1LOCK = 0 in FLASH_SR

OEM2KEY can be modified:

- In readout protection level 0 or 0.5
- In readout protection level 1 if OEM2LOCK = 0 in FLASH_SR

When attempting to modify FLASH_OEM1KEYRx or FLASH_OEM2KEYRx without following these rules, the user option modification is not done and the OPTWERR bit is set.

In order to activate OEM1 lock mechanism, the following steps are needed:

1. Check that the OEM1LOCK bit is not set or that the readout protection is at level 0.
2. Write a 128-bit key in FLASH_OEM1KEYRx
3. Check key CRC thanks to OEM1KEYCRC.
4. Launch option modification by setting the OPTSTRT bit in FLASH_CR.
5. Wait for the BSY bit to be cleared and check that OPTWERR is not set.

6. Set the OBL_LAUNCH option bit to start option-byte loading or perform a power-on reset.
7. Check that OEM1LOCK is set.

In order to activate OEM2 lock mechanism, the following steps are needed:

1. Check that the OEM2LOCK bit is not set or that the readout protection is at level 0 or 0.5.
2. Write a 128-bit key in FLASH_OEM2KEYRx.
3. Check key CRC using OEM2KEYCRC.
4. Launch option modification by setting the OPTSTRT bit in FLASH_CR.
5. Wait for the BSY bit to be cleared and check that OPTWERR is not set.
6. Set the OBL_LAUNCH option bit to start option-byte loading or perform a power-on reset.
7. Check that OEM2LOCK is set.

Note: The OEM1KEY and OEM2KEY must contain more than four 0.

It is recommended to always activate OEM2 lock mechanism even if no regression level is expected.

Once set, the RDP transition with OEM keys mechanism cannot be disabled. This means that the OEM keys can be modified, but never cleared.

OEM1 RDP lock mechanism

The OEM1 RDP lock mechanism is active when the OEM1LOCK bit is set. It blocks the RDP level 1 to RDP level 0 regression.

In order to regress from RDP level 1 to RDP level 0, the following unlock sequence must be applied:

1. Shift OEM1KEY[31:0], OEM1KEY[63:32], OEM1KEY[95:64] and then OEM1KEY[127:96] through JTAG or SWD in DBGMCU_DBG_AUTH_HOST.
2. If this key matches the OEM1KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
3. If the key does not match the OEM1KEY value, the RDP regression and any access to the flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 1 to RDP level 0 without following this sequence sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM1LOCK = 0), the regression from RDP level 1 to RDP level 0 is always granted.

OEM2 RDP lock mechanism

The OEM2 RDP lock mechanism is active when the OEM2LOCK bit is set. It allows the following actions:

- Block RDP level 1 to RDP level 0.5 regression.
- Authorize RDP level 2 to RDP level 1 regression.

In order to regress from RDP level 1 to RDP level 0.5, the following unlock sequence must be applied:

1. Shift OEM2KEY[31:0], OEM2KEY[63:32], OEM2KEY[95:64], and then OEM2KEY[127:96] through JTAG or SWD under reset in DBGMCU_DBG_AUTH_HOST.
2. Release reset if this key matches the OEM2KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
3. If the key does not match the OEM2KEY value, the RDP regression and any access to the flash memory are blocked until a next power-on reset to reload option bytes.

In order to regress from RDP level 2 to RDP level 1, the following unlock sequence must be applied:

1. Shift OEM2KEY[31:0], OEM2KEY[63:32], OEM2KEY[95:64], and then OEM2KEY[127:96] through JTAG or SWD under reset in DBGMCU_DBG_AUTH_HOST register
2. Release reset if this key matches the OEM2KEY value:
   – The RDP regression is launched by hardware (it is not possible to execute instructions when the key is matching).
   – Apply a power-on reset (cycle V_{DD} power supply OFF and ON).
3. If the key does not match the OEM2KEY value, the RDP regression and any access to the flash memory are blocked until a next power-on reset to reload option bytes.

Attempting to regress from RDP level 2 to RDP level 1 without following these sequences, leaves option bytes unchanged.

Attempting to regress from RDP level 1 to RDP level 0.5 without following these sequences, sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM2LOCK = 0), the following happens:

- The regression from RDP level 1 to RDP level 0.5 is always granted.
- The regression from RDP level 2 to RDP level 1 is never granted. When attempting to modify the options bytes, the protection error flag OPTWERR is set in FLASH_SR, and an interrupt can be generated.

OEM Key CRC source

Below is the CRC source code that can be used to compare with the result of the computation provided by the flash interface in OEM1KEYCRC (resp. OEM2KEYCRC) bitfield after loading the keys in FLASH OEM1 (resp. OEM2) Key registers.

```
uint8_t getCRC(uint32_t * keyin)
{
const uint8_t CRC7_POLY = 0x7;
const uint32_t key_strobe[4] = {0xAA55AA55, 0x3, 0x18, 0xC0}; uint8_t i, j,
k, crc = 0x0;
uint32_t keyval;
for (j = 0; j < 4; j++)
{
keyval = *(keyin+j);
if (j == 0) { keyval ^= key_strobe[0]; }
else { keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8)
| crc; } for (i = 0, crc = 0; i < 32; i++)
```

```
{
k = (((crc >> 7) ^ (keyval >> (31-i))&0xF)) & 1; crc <<= 1;
if (k) { crc ^= CRC7_POLY; }
}
crc^=0x55;
}
return crc;
}
```

7.7 System memory

System memory stores RSS (root secure services) firmware programmed by STMicroelectronics during production. RSS provides runtime services to user firmware. When TrustZone® is enabled (user sets the TZEN bitfield to 1), RSS provides secure services to the secure user firmware only. When TrustZone® is disabled (user sets the TZEN bitfield to 0), RSS does not provide nonsecure services to the user firmware.

7.7.1 RSS user functions

The RSS provides runtime services using the RSS library, whose functions are exposed to the user within the CMSIS device header file, provided by the STM32Cube firmware package.

RSS provides services through the RSSLIB library, dedicated to secure user firmware when the system is configured with TrustZone® enabled (TZEN bitfield set to 1).

Table 53. Macros for RSS services

TrustZone	C defined macro	Location in flash memory
Enabled	RSSLIB_PFUNC	0x0BF99040
Disabled	NA	NA

RSSLIB

The secure user firmware calls the RSSLIB functions using RSSLIB_PFUNC C-defined macro, which points to a location within the nonsecure system memory. Before calling the RSSLIB functions, the secure user firmware must define a nonsecure region above this location within SAU of the Cortex®-M33 processor, starting from RSSLIB_SYS_FLASH_NS_PFUNC_START (0x0BF99040), up to RSSLIB_SYS_FLASH_NS_PFUNC_END (0x0BF990FF). These last addresses are provided within the CMSIS device header file.

The user can configure this nonsecure region either by using the CMSIS system partition header file, or by implementing their own code for SAU setup. The CMSIS system partition header file is part of the STM32Cube firmware package.

Table 54. RSS lib interface functions

Library	Function	Attributes
RSSLIB_PFUNC	CloseExitHDP	Secure callable function
	CloseExitHDPExt	

CloseExitHDP

Secure attribute:

- secure callable function

Prototype:

- uint32_t CloseExitHDP (uint32_t HdpArea, uint32_t VectorTableAddr);

Arguments:

- HdpArea: notifies which hdp area to close, can be a combination of hdpa area 1 and hdp area 2
- VectorTableAddr: a pointer on the vector table containing the reset handler the function jumps to

Returned values:

- 0xF5F5F5F5U: error on input parameter
- otherwise, does not return

CloseExitHDP closes the requested hdp area passed in input parameter and jumps to the reset handler present within the vector table. The function does not return on successful execution.

CloseExitHDPExt

Secure attribute:

- secure callable function

Prototype:

- uint32_t CloseExitHDPExt (uint32_t HdpExtArea, uint32_t VectorTableAddr, uint32_t CloseBound);

Arguments:

- HdpExtArea: notifies which hdp extension area to close, can be a combination of hdp extension area 1 and hdp extension area 2
- VectorTableAddr: pointer on the vector table containing the reset handler the function jumps to
- CloseBound: notifies if the HDP extension area should be closed with HDPx_EXT increment allowed or not

Returned values:

- 0xF5F5F5F5U: error on input parameter
- Otherwise, does not return

CloseExitHDPExt closes the requested hdp extension area passed in input parameter and jumps to the reset handler present within the vector table. The function does not return on successful execution.

7.8 Summary of flash memory and flash memory registers access control

The flash interface evaluates the access restrictions in the following orders: RDP level, TrustZone security, write protection (for write access), HDP, and privilege. The tables below summarize all the flash memory and registers accesses status versus RDP level, WRP and HDP protections.

Table 55. Flash memory access versus RDP level when TrustZone is active (TZEN = 1)

<table>
<tr><th colspan="2" rowspan="2">Access type</th><th colspan="2">RDP level 0, RDP level 0.5, RDP level 1 no intrusion(1), or RDP level 2</th><th>RDP level 1 with intrusion(2)</th></tr>
<tr><th>Nonsecure page</th><th>Secure page</th><th>Nonsecure or secure page</th></tr>
<tr><td rowspan="4">Secure</td><td>Fetch</td><td>Bus error</td><td rowspan="2">OK</td><td rowspan="2">Bus error</td></tr>
<tr><td>Read</td><td>RAZ, flash illegal access event</td></tr>
<tr><td>Write</td><td rowspan="2">WI, secure WRPERR flag set, flash illegal access event</td><td rowspan="2">No WRP: OK
WRP pages: WI and secure WRPERR flag set</td><td rowspan="2">WI, secure WRPERR flag set</td></tr>
<tr><td>Page erase</td></tr>
<tr><td rowspan="4">Nonsecure</td><td>Fetch</td><td rowspan="2">OK</td><td>Bus error</td><td rowspan="2">Bus error</td></tr>
<tr><td>Read</td><td>RAZ, flash illegal access event</td></tr>
<tr><td>Write</td><td rowspan="2">No WRP: OK
WRP pages: WI and nonsecure WRPERR flag set</td><td rowspan="2">WI, non secure WRPERR flag set, flash illegal access event</td></tr>
<tr><td>Page erase</td><td>WI, nonsecure WRPERR flag set</td></tr>
</table>

1. RDP level 1 no intrusion = when booting from user flash memory and no debug access.
2. RDP level 1 with intrusion = when debug access detected.

Table 56. Flash memory access versus HDPx and HDPx extended (x = 1 or 2)

Access type	Flash memory area			
	HDPx (with x = 1,2)	HDP1Ext	HDP2Ext	Others
fetch	OK if HDPx is open(1) else RAZ	OK if HDP1Ext is open(2) and HDP1 and HDP2 closed or not defined, else RAZ	OK if HDP2Ext is open and HDP1 and HDP2 closed or not defined, else RAZ	OK if HDP1, HDP2, HDP1Ext and HDP2Ext are closed or not defined, else RAZ
Read	OK if HDPx is open, else RAZ	OK if HDP1Ext is open, else RAZ	OK if HDP2Ext is open, else RAZ	OK
Write/ page erase	OK if HDPx open, else WI, secure WRPERR flag set	OK if HDP1Ext is open, else WI, secure WRPERR flag set	OK if HDP2Ext is open, else WI, secure WRPERR flag set	OK

1. “HDPx area is open" means that HDPx_ACCDIS = HDPxExt_ACCDIS = 0xA3. Otherwise, it is closed. "HDPx area is defined" is described in *Table 44*.
2. HDPxExt is open" means that HDPxExt_ACCDIS = 0xA3. Otherwise, it is closed. When HDPxExt is closed (HDPxExt_ACCDIS ≠ 0xA3), HDPx is automatically closed. "HDPxExt area is not defined" is described in *Table 46*.

Table 57. Flash memory access versus RDP level when TrustZone is disabled (TZEN = 0)

Access type	RDP level 0, RDP level 1 no intrusion, or RDP level 2[1]	RDP level 1 with intrusion[2]
Fetch	OK	Bus error
Read		
Write	No WRP: OK WRP pages: WI and nonsecure WRPERR flag set	
Erase		WI and nonsecure WRPERR flag set

1. RDP level 1 no intrusion = when booting from user flash memory and no debug access.
2. RDP level 1 with intrusion = when booting from RAM or system memory or debug access detected.

Table 58. Flash memory mass erase versus RDP level when TrustZone is active (TZEN = 1)

Access type		RDP level 0, RDP level 0.5, RDP level 1 no intrusion or RDP level 2[1]					RDP level 1 with intrusion[2]
		Nonsecure flash memory	Secure flash memory			Mix nonsecure and secure flash memory	Nonsecure or secure flash memory
			HDP area (HDPxEN≠0xB4 HDPx_ ACCDIS≠0xA3)	HDP extension area (HDPxEXT_ ACCDIS≠0xA3)	Others[3]		
Secure	Bank or mass erase	WI, secure WRPERR flag set, flash memory illegal access event	WI, secure WRPERR flag set	WI, secure WRPERR flag set	No WRP: OK WRP pages: WI and secure WRPERR flag set	WI, secure WRPERR flag set, flash memory illegal access event	WI, secure WRPERR flag set
Non secure		No WRP: OK WRP pages: WI and nonsecure WRPERR flag set	WI, nonsecure WRPERR flag set, flash memory illegal access event				WI, nonsecure WRPERR flag set

1. RDP level 1 no intrusion = when booting from user flash memory and no debug access.
2. RDP level 1 with intrusion = when debug access detected.
3. “Others” refers to the other flash memory secure configurations than the one described for HDP protections or for HDP extension protection. Example: flash memory secure and HDPx area enabled but HDPx_ACCDIS = 0xA3, or flash memory secure and HDPx extension area defined but HDPxEXT_ACCDIS = 0xA3.

Table 59. Flash system memory, OTP and RSS accesses (valid for all RDP levels)

Access type		System memory (bootloader)	OTP	RSS
Secure (TZEN = 1)	Fetch	Bus error		RAZ
	Read	RAZ, flash memory register illegal access event	OK	
	Write	WI, secure WRPERR flag set, flash memory illegal access event		WI, secure WRPERR flag set

Table 59. Flash system memory, OTP and RSS accesses (valid for all RDP levels) (continued)

Access type		System memory (bootloader)	OTP	RSS
Nonsecure (TZEN = 0 or TZEN = 1)	Fetch	OK	Bus error	Bus error
	Read		OK	RAZ(1)
	Write	WI and nonsecure WRPERR flag set	OK if not virgin: WI, nonsecure PROGERR flag set	WI, nonsecure WRPERR flag set

1. Flash memory illegal access event is generated when TZEN = 1.

Table 60. FLASH registers access(1)

Access type			Nonsecure register		Secure register	
			PRIV = 1	PRIV = 0	SPRIV = 1	SPRIV = 0
Fetch	Secure/ nonsecure	Privileged/ unprivileged	Bus error			
Read/ Write	Secure(2)	Privileged	OK			
		Unprivileged	RAZ/WI	OK	RAZ/WI	OK
	Nonsecure(3)	Privileged	OK		RAZ/WI and a flash memory register illegal access event(4)	
		Unprivileged	RAZ/WI	OK		

1. Except FLASH_SECBByRx, FLASH_PRIVBByRx ,and FLASH_PRIVCFGR.
2. Secure access is only valid when TrustZone is active (TZEN = 1).
3. Nonsecure access are valid when TrustZone is active or disabled.
4. Flash register illegal access event is only generated when TZEN = 1.

Table 61. FLASH page access versus privilege mode(1)

Access type		Unprivileged page	Privileged page
Fetch, read/write, page erase	Privileged	OK	
Fetch, read	Unprivileged	OK	RAZ
Write, page erase	Unprivileged		WI, secure or nonsecure WRPERR flag set

1. When TZEN = 1, access must be granted by security firewall before privilege is considered

Table 62. FLASH mass erase versus privilege mode(1)

Access type		Unprivileged flash memory	Privileged flash memory	Mix unprivileged and privileged flash memory
Mass erase	Privileged	OK		
Mass erase	Unprivileged	OK	WI, secure or nonsecure WRPERR flag set	

1. When TZEN = 1, access must be granted by security firewall before privilege is considered

Table 63. FLASH_SECBByRx registers access when TrustZone is active (TZEN = 1)

Access type			Bit i in FLASH_PRIVBByRx	Bit i in FLASH_SECBByRx
Fetch	Secure/nonsecure	Privileged/unprivileged	-	Bus error
Read	Secure/nonsecure	Privileged/unprivileged	-	OK
Write	Secure	Privileged	-	OK
		Unprivileged	0	OK for bit i
		Unprivileged	1	WI for bit i
	Nonsecure	Privileged/unprivileged	-	WI and a flash memory register illegal access event

Table 64. FLASH_PRIVBByRx registers access when TrustZone is active (TZEN = 1)

Access type			Page secure state (watermark or blocked based)	Bit i in FLASH_PRIVBByRx
Fetch	Privileged/unprivileged	Secure/nonsecure	-	Bus error
Read	Privileged/unprivileged	Secure/nonsecure	-	OK for all bits
Write	Privileged	Secured	-	OK for all bits
		Nonsecure	Nonsecure	OK for bit i
		Nonsecure	Secure	WI for bit i
	Unprivileged	Secured/nonsecure	-	WI for all bits

Table 65. FLASH_PRIVBByRx registers access when TrustZone is disabled (TZEN = 0)

Access type		FLASH_PRIVBByRx
Fetch	Privileged/unprivileged	Bus error
Read	Privileged/unprivileged	OK
Write	Privileged	OK
	Unprivileged	WI

7.9 FLASH interrupts

Table 66. Flash interrupt requests

Interrupt vector	Interrupt event	Event flag	Event flag/interrupt clearing method	Interrupt enable control bit	Exit Sleep mode	Exit Stop and Standby modes
FLASH_S	Secure end of operation	Secure EOP(1)	Write secure EOP = 1	Secure EOPIE	Yes	No
	Secure operation error	Secure OPERR(2)	Write secure OPERR = 1	Secure ERRIE	Yes	No

Table 66. Flash interrupt requests (continued)

Interrupt vector	Interrupt event	Event flag	Event flag/interrupt clearing method	Interrupt enable control bit	Exit Sleep mode	Exit Stop and Standby modes
FLASH	Nonsecure end of operation	Nonsecure EOP(1)	Write nonsecure EOP = 1	Nonsecure EOPIE	Yes	No
	Nonsecure operation error	Nonsecure OPERR(2)	Write nonsecure OPERR = 1	Nonsecure ERRIE	Yes	No
	ECC correction	ECCC	Write ECCC = 1	ECCCIE	Yes	No

1. Secure EOP (resp. nonsecure EOP) is set only if secure EOPIE (resp. nonsecure EOPIE) is set.
2. Secure OPERR (resp. nonsecure OPERR) is set only if secure ERRIE (resp. nonsecure ERRIE) is set.

7.10 FLASH registers

7.10.1 FLASH access control register (FLASH_ACR)

Address offset: 0x00

Reset value: 0x0000 0001

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state when no flash memory read is ongoing; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SLEEP_PD	PDREQ2	PDREQ1	LPM	Res.	Res.	PRFTEN	Res.	Res.	Res.	Res.	LATENCY[3:0]			
	rw	rs	rs	rw			rw					rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **SLEEP_PD**: Flash memory power-down mode during Sleep mode

This bit determines whether the flash memory is in power-down mode or Idle mode when the device is in Sleep mode.

0: Flash in Idle mode during Sleep mode

1: Flash in power-down mode during Sleep mode

Caution: The flash must not be put in power-down while a program or an erase operation is ongoing.

Bit 13 **PDREQ2**: Bank 2 power-down mode request

This bit is write-protected with FLASH_PDKEY2R. This bit requests bank 2 to enter power-down mode. When bank 2 enters power-down mode, this bit is cleared by hardware and FLASH_PDKEY2R is locked.

0: No request for bank 2 to enter power-down mode

1: Bank 2 requested to enter power-down mode

Bit 12 **PDREQ1**: Bank 1 power-down mode request
This bit is write-protected with FLASH_PDKEY1R. This bit requests bank 1 to enter power-down mode. When bank 1 enters power-down mode, this bit is cleared by hardware and FLASH_PDKEY1R is locked.
0: No request for bank 1 to enter power-down mode
1: Bank 1 requested to enter power-down mode

Bit 11 **LPM**: Low-power read mode
This bit puts the flash memory in low-power read mode.
0: FLASH not in low-power read mode
1: FLASH in low-power read mode

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **PRFTEN**: Prefetch enable
This bit enables the prefetch buffer in the embedded flash memory.
0: Prefetch disabled
1: Prefetch enabled

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **LATENCY[3:0]**: Latency
This bitfield represents the ratio between the HCLK (AHB clock) period and the flash memory access time.
0000: 0 wait state
0001: 1 wait state
0010: 2 wait states
...
1111: 15 wait states

7.10.2 FLASH nonsecure key register (FLASH_KEYR)

Address offset: 0x08

Reset value: 0x0000 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV =1 in FLASH_PRIVCFGR register.

Access: one wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Flash memory nonsecure key
The following values must be written consecutively to unlock the FLASH_CR register, allowing flash memory nonsecure programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

7.10.3 FLASH secure key register (FLASH_SKEYR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Access: one wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Flash memory secure key

The following values must be written consecutively to unlock the FLASH_SCR register, allowing flash memory secure programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

7.10.4 FLASH option key register (FLASH_OPTKEYR)

Address offset: 0x10

Reset value: 0x0000 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: one wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Option-byte key

The following values must be written consecutively to unlock the FLASH_OPTR register allowing option-byte programming/erasing operations:
KEY1: 0x0819 2A3B
KEY2: 0x4C5D 6E7F

7.10.5 FLASH bank 1 power-down key register (FLASH_PDKEY1R)

Address offset: 0x18

Reset value: 0x0000 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY1[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY1[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY1[31:0]**: Bank 1 power-down key

The following values must be written consecutively to unlock PDREQ1 bit in FLASH_ACR:
KEY1_1: 0x0415 2637
KEY1_2: 0xFAFB FCFD

7.10.6 FLASH bank 2 power-down key register (FLASH_PDKEY2R)

Address offset: 0x1C

Reset value: 0x0000 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY2[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY2[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY2[31:0]**: Bank 2 power-down key

The following values must be written consecutively to unlock PDREQ2 bit in FLASH_ACR:
KEY2_1: 0x4051 6273
KEY2_2: 0xAFBF CFDF

7.10.7 FLASH nonsecure status register (FLASH_SR)

Address offset: 0x20

Reset value: 0x000X 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PD2	PD1	OEM2LOCK	OEM1LOCK	WDW	BSY
										r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	OPTWERR	Res.	Res.	Res.	Res.	Res.	PGSERR	SIZERR	PGAERR	WRPERR	PROGERR	Res.	OPERR	EOP
		rc_w1						rc_w1	rc_w1	rc_w1	rc_w1	rc_w1		rc_w1	rc_w1

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **PD2**: Bank 2 in power-down mode

This bit indicates that the flash memory bank 2 is in power-down state. It is reset when bank 2 is in normal mode or being awaken.

Bit 20 **PD1**: Bank 1 in power-down mode

This bit indicates that the flash memory bank 1 is in power-down state. It is reset when bank 1 is in normal mode or being awaken.

Bit 19 **OEM2LOCK**: OEM2 lock

This bit indicates that the OEM2 RDP key read during the OBL is not virgin. When set, the OEM2 RDP lock mechanism is active.

Bit 18 **OEM1LOCK**: OEM1 lock

This bit indicates that the OEM1 RDP key read during the OBL is not virgin. When set, the OEM1 RDP lock mechanism is active.

Bit 17 **WDW**: Nonsecure wait data to write

This bit indicates that the flash memory write buffer has been written by a secure or nonsecure operation. It is set when the first data is stored in the buffer, and cleared when the write is performed in the flash memory.

Bit 16 **BSY**: Nonsecure busy

This bit indicates that a flash memory secure or nonsecure operation is in progress. It is set at the beginning of a flash operation, and reset when the operation finishes or when an error occurs.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OPTWERR**: Option write error

This bit is set by hardware when the options bytes are written with an invalid configuration. It is cleared by writing 1. Refer to *Section 7.3.8: Flash memory errors flags* for full conditions of error flag setting.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **PGSERR**: Nonsecure programming sequence error

This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1. Refer to *Section 7.3.8: Flash memory errors flags* for full conditions of error flag setting.

Bit 6 **SIZERR**: Nonsecure size error

This bit is set by hardware when the size of the access is a byte or half-word during a nonsecure program sequence. Only double-word programming is allowed by means of successive word accesses. This bit is cleared by writing 1.

Bit 5 **PGAERR**: Nonsecure programming alignment error

This bit is set by hardware when the first word to be programmed is not aligned with a double-word address, or the second does not belong to the same double-word address. This bit is cleared by writing 1.

Bit 4 **WRPERR**: Nonsecure write protection error

This bit is set by hardware when a nonsecure address to be erased/programmed belongs to a write-protected part (by WRP, HDP, or RDP level 1) of the flash memory. This bit is cleared by writing 1. Refer to *Section 7.3.8: Flash memory errors flags* for full conditions of error flag setting.

Bit 3 **PROGERR**: Nonsecure programming error

This bit is set by hardware when a nonsecure double-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Nonsecure operation error

This bit is set by hardware when a flash memory nonsecure operation (program/erase) completes unsuccessfully. This bit is set only if nonsecure error interrupts are enabled (ERRIE = 1 in FLASH_CR). This bit is cleared by writing 1.

Bit 0 **EOP**: Nonsecure end of operation

This bit is set by hardware when one or more flash memory nonsecure operation (program/erase) has been completed successfully. This bit is set only if the nonsecure end of operation interrupts are enabled (EOPIE = 1 in FLASH_CR). This bit is cleared by writing 1.

7.10.8 FLASH secure status register (FLASH_SSR)

Address offset: 0x24

Reset value: 0x0000 0000

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WDW	BSY
														r	r

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PGSERR	SIZERR	PGAERR	WRPERR	PROGERR	Res.	OPERR	EOP
								rc_w1	rc_w1	rc_w1	rc_w1	rc_w1		rc_w1	rc_w1

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **WDW**: Secure wait data to write

This bit indicates that the flash memory write buffer has been written by a secure or nonsecure operation. It is set when the first data is stored in the buffer, and cleared when the write is performed in the flash memory.

Bit 16 **BSY**: Secure busy

This bit indicates that a flash memory secure or nonsecure operation is in progress. This is set on the beginning of a flash operation, and reset when the operation finishes or when an error occurs.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **PGSERR**: Secure programming sequence error

This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1. Refer to *Section 7.3.8: Flash memory errors flags* for full conditions of error flag setting.

Bit 6 **SIZERR**: Secure size error

This bit is set by hardware when the size of the access is a byte or half-word during a secure program sequence. Only double-word programming is allowed by means of successive word accesses.This bit is cleared by writing 1.

Bit 5 **PGAERR**: Secure programming alignment error

This bit is set by hardware when the first word to be programmed is not aligned with a double-word address, or the second word does not belong to the same double-word address.This bit is cleared by writing 1.

Bit 4 **WRPERR**: Secure write protection error

This bit is set by hardware when a secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP, or RDP level 1) of the flash memory.This bit is cleared by writing 1. Refer to *Section 7.3.8: Flash memory errors flags* for full conditions of error flag setting.

Bit 3 **PROGERR**: Secure programming error

This bit is set by hardware when a secure double-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Secure operation error

This bit is set by hardware when a flash memory secure operation (program/erase) completes unsuccessfully. This bit is set only if secure error interrupts are enabled (ERRIE = 1 in FLASH_SCR). This bit is cleared by writing 1.

Bit 0 **EOP**: Secure end of operation

This bit is set by hardware when one or more flash memory secure operation (program/erase) has been completed successfully. This bit is set only if the secure end of operation interrupts are enabled (EOPIE = 1 in FLASH_SCR). This bit is cleared by writing 1.

7.10.9 FLASH nonsecure control register (FLASH_CR)

Address offset: 0x28

Reset value: 0xC000 0000

This register can only be written when the BSY or OBL_LAUNCH are reset. Otherwise, the write access is stalled until the BSY bits are reset.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state when no flash memory operation is ongoing; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	OPTLOCK	Res.	Res.	OBL_LAUNCH	Res.	ERRIE	EOPIE	Res.	Res.	Res.	Res.	Res.	Res.	OPTSTRT	STRT
rs	rs			rc_w1		rw	rw							rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MER2	BWR	Res.	Res.	BKER	Res.	PNB[6:0]							MER1	PER	PG
rw	rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK:** Nonsecure lock

This bit is set only. When set, the FLASH_CR register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_KEYR register.

In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30 **OPTLOCK:** Option lock

This bit is set only. When set, all bits concerning user options in FLASH_CR register are locked. This bit is cleared by hardware after detecting the unlock sequence. The LOCK bit in FLASH_CR must be cleared before doing the unlock sequence for OPTLOCK bit.

In case of an unsuccessful unlock operation, this bit remains set until the next reset.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **OBL_LAUNCH**: Option-byte loading forced

When set to 1, this bit forces the option-byte reloading. This bit is cleared only when the option-byte loading is complete. It cannot be written if OPTLOCK is set.

0: Option-byte loading complete

1: Option-byte loading requested

Bit 26 Reserved, must be kept at reset value.

Bit 25 **ERRIE**: Nonsecure error interrupt enable

This bit enables the interrupt generation when the OPERR bit in FLASH_SR is set to 1.

0: Nonsecure OPERR error interrupt disabled

1: Nonsecure OPERR error interrupt enabled

Bit 24 **EOPIE**: Nonsecure end of operation interrupt enable

This bit enables the interrupt generation when the EOP bit in FLASH_SR is set to 1.

0: Nonsecure EOP Interrupt disabled

1: Nonsecure EOP Interrupt enabled

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **OPTSTRT**: Option modification start
This bit triggers an option operation when set. It can not be written if OPTLOCK bit is set. This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.

Bit 16 **STRT**: Nonsecure start
This bit triggers a nonsecure erase operation when set. If MER1, MER2, and PER bits are reset, and the STRT bit is set (this configuration is forbidden), the PGSERR bit in FLASH_SR is set .
This bit is set only by software and is cleared when the BSY bit is cleared in FLASH_SR.

Bit 15 **MER2**: Nonsecure bank 2 mass erase
This bit triggers the bank 2 nonsecure mass erase (all bank 2 user pages) when set.

Bit 14 **BWR**: Nonsecure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Nonsecure bank selection for page erase
0: Bank 1 selected for nonsecure page erase
1: Bank 2 selected for nonsecure page erase

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Nonsecure page number selection
These bits select the page to erase.
0000000: page 0
0000001: page 1
...
1111111: page 127

Bit 2 **MER1**: Nonsecure bank 1 mass erase
This bit triggers the bank 1 nonsecure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Nonsecure page erase
0: Nonsecure page erase disabled
1: Nonsecure page erase enabled

Bit 0 **PG**: Nonsecure programming
0: Nonsecure FLASH programming disabled
1: Nonsecure FLASH programming enabled

7.10.10 FLASH secure control register (FLASH_SCR)

Address offset: 0x2C

Reset value: 0x8000 0000

This register can only be written when the BSY or OBL_LAUNCH are reset. Otherwise, the write access stalls until the BSY bits are reset.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state when no flash memory operation is ongoing; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	INV	Res.	Res.	Res.	ERRIE	EOPIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRT
rs		rw				rw	rw								rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MER2	BWR	Res.	Res.	BKER	Res.	PNB[6:0]							MER1	PER	PG
rw	rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK:** Secure lock

This bit is set only. When set, the FLASH_SCR register is locked. This bit is cleared by hardware after detecting the unlock sequence in FLASH_SKEYR register.
In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **INV:** Flash memory security state invert

This bit inverts the flash memory security state.

Bits 28:26 Reserved, must be kept at reset value.

Bit 25 **ERRIE**: Secure error interrupt enable

This bit enables the interrupt generation when the OPERR bit in FLASH_SSR is set to 1.
0: Secure OPERR error interrupt disabled
1: Secure OPERR error interrupt enabled

Bit 24 **EOPIE**: Secure end of operation interrupt enable

This bit enables the interrupt generation when the EOP bit in FLASH_SSR is set to 1.
0: Secure EOP Interrupt disabled
1: Secure EOP Interrupt enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **STRT**: Secure start

This bit triggers a secure erase operation when set. If MER1, MER2, and PER bits are reset, and the STRT bit is set, the PGSERR in FLASH_SSR is set (this condition is forbidden).
This bit is set only by software and is cleared when the BSY bit is cleared in FLASH_SSR.

Bit 15 **MER2**: Secure bank 2 mass erase

This bit triggers the bank 2 secure mass erase (all bank 2 user pages) when set.

Bit 14 **BWR**: Secure burst write programming mode

When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Secure bank selection for page erase
0: Bank 1 selected for secure page erase
1: Bank 2 selected for secure page erase

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Secure page number selection
These bits select the page to erase:
0000000: page 0
0000001: page 1
...
1111111: page 127

Bit 2 **MER1**: Secure bank 1 mass erase
This bit triggers the bank 1 secure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Secure page erase
0: Secure page erase disabled
1: Secure page erase enabled

Bit 0 **PG**: Secure programming
0: Secure FLASH programming disabled
1: Secure FLASH programming enabled

7.10.11 FLASH ECC register (FLASH_ECCCORR)

Address offset: 0x30

Reset value: 0x0000 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	ECCC	Res.	Res.	Res.	Res.	Res.	ECCIE	Res.	SYSF_ECC	BK_ECC	Res.	Res.	ADDR_ECC[18:16]		
	rc_w1						rw		r	r			r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ECCC**: ECC correction
This bit is set by hardware when one ECC error has been detected and corrected (only if ECCC was previously cleared). An interrupt is generated if ECCIE is set. This bit is cleared by writing 1.

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **ECCIE**: ECC correction interrupt enable
This bit enables the interrupt generation when the ECCC bit in FLASH_ECCR is set.
0: ECCC interrupt disabled
1: ECCC interrupt enabled.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SYSF_ECC**: System flash memory ECC fail

This bit indicates that the ECC error correction or double ECC error detection is located in the system flash memory.

Bit 21 **BK_ECC**: ECC fail bank

This bit indicates which bank is concerned by the ECC error correction.
0: Bank 1
1: Bank 2

Bits 20:19 Reserved, must be kept at reset value.

Bits 18:0 **ADDR_ECC[18:0]**: ECC fail address

This bitfield indicates which address is concerned by the ECC error correction. The address is given by bank from address 0x0 0000 to 0x7 FFF8.

7.10.12 FLASH ECC detection register (FLASH_ECCDETR)

Address offset: 0x34

Reset value: 0x0000 0000

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ECCD**: ECC detection

This bit is set by hardware when two ECC errors have been detected (only if ECCD was previously cleared). When this bit is set, a NMI is generated. This bit is cleared by writing 1.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **SYSF_ECC**: System flash memory ECC fail

This bit indicates that the double ECC error detection is located in the system flash memory.

Bit 21 **BK_ECC**: ECC fail bank

This bit indicates which bank is concerned by the double ECC error detection.
0: Bank 1
1: Bank 2

Bits 20:19 Reserved, must be kept at reset value.

Bits 18:0 **ADDR_ECC[18:0]**: ECC fail address

This bitfield indicates which address is concerned by the double ECC error detection. The address is given by bank from address 0x0 0000 to 0x7 FFF8.

7.10.13 FLASH operation status register (FLASH_OPSR)

Address offset: 0x38

Reset value: 0xX0XX XXXX

System reset value: 0xX0XX XXXX

Power-on reset value: 0xX0XX XXXX

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CODE_OP[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	SYSF_OP	BK_OP	Res.	Res.	ADDR_OP[18:16]

ADDR_OP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 **CODE_OP[2:0]**: Flash memory operation code

This bitfield indicates which flash memory operation has been interrupted by a system reset:
000: No flash operation interrupted by previous reset
001: Single write operation interrupted
010: Burst write operation interrupted
011: Page erase operation interrupted
100: Bank erase operation interrupted
101: Mass erase operation interrupted
110: Option change operation interrupted
111: Reserved

Bits 28:23 Reserved, must be kept at reset value.

Bit 22 **SYSF_OP**: Operation in system flash memory interrupted

This bit indicates that the reset occurred during an operation in the system flash memory.

Bit 21 **BK_OP**: Interrupted operation bank

This bit indicates which flash memory bank was accessed when reset occurred
0: Bank 1
1: Bank 2

Bits 20:19 Reserved, must be kept at reset value.

Bits 18:0 **ADDR_OP[18:0]**: Interrupted operation address

This bitfield indicates which address in the flash memory was accessed when reset occurred. The address is given by bank from address 0x0 0000 to 0x7 FFF8.

7.10.14 FLASH option register (FLASH_OPTR)

Address offset: 0x40

Reset value: 0xXXXX XXXX

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0x1FEF F0AA

(register bits 0 to 31 are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TZEN:** Global TrustZone security enable
0: Global TrustZone security disabled
1: Global TrustZone security enabled

Bit 30 **IO_VDDIO2_HSLV:** High-speed I/O at low V_{DDIO2} voltage configuration bit
This bit can be set only with V_{DDIO2} below 2.5 V.
0: High-speed I/O at low V_{DDIO2} voltage feature disabled (V_{DDIO2} can exceed 2.5 V)
1: High-speed I/O at low V_{DDIO2} voltage feature enabled (V_{DDIO2} remains below 2.5 V)

Bit 29 **IO_VDD_HSLV:** High-speed I/O at low V_{DD} voltage configuration bit
This bit can be set only with V_{DD} below 2.5V
0: High-speed I/O at low V_{DD} voltage feature disabled (V_{DD} can exceed 2.5 V)
1: High-speed I/O at low V_{DD} voltage feature enabled (V_{DD} remains below 2.5 V)

Bit 28 Reserved, must be kept at reset value.

Bit 27 **NBOOT0:** NBOOT0 option bit
0: NBOOT0 = 0
1: NBOOT0 = 1

Bit 26 **NSWBOOT0:** Software BOOT0
0: BOOT0 taken from the option bit NBOOT0
1: BOOT0 taken from PH3/BOOT0 pin

Bit 25 **SRAM2_RST:** SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs

Bit 24 **SRAM2_PE:** SRAM2 parity check enable
0: SRAM2 parity check enabled
1: SRAM2 parity check disabled

Bits 23:22 **BL_IO_VDDIO2_HSLV[1:0]:** Enable HSLV on PG2, PG3, PG4, and PG5 when bootloader is running.
00: High-speed I/O at low V_{DDIO2} voltage feature enabled (V_{DDIO2} remains below 2.5 V)
11: High-speed I/O at low V_{DDIO2} voltage feature disabled (V_{DDIO2} can exceed 2.5 V)
Others: Reserved.

Bit 21 **DUALBANK:** Dual-bank configuration
0: Single-bank FLASH with contiguous address in bank 1
1: Dual-bank FLASH with contiguous addresses

Bit 20 **SWAP_BANK:** Swap banks
0: Bank 1 and bank 2 addresses not swapped
1: Bank 1 and bank 2 addresses swapped

Bit 19 **WWDG_SW:** Window watchdog selection
0: Hardware WWDG selected
1: Software WWDG selected

Bit 18 **IWDG_STDBY:** Independent watchdog counter freeze in Standby mode
0: IWDG counter frozen in Standby mode
1: IWDG counter running in Standby mode

Bit 17 **IWDG_STOP:** Independent watchdog counter freeze in Stop mode
0: IWDG counter frozen in Stop mode
1: IIWDG counter running in Stop mode

Bit 16 **IWDG_SW:** Independent watchdog selection
0: Hardware IWDG selected
1: Software IWDG selected

Bit 15 **SRAM1_RST:** SRAM1 erase upon system reset
0: SRAM1 erased when a system reset occurs
1: SRAM1 not erased when a system reset occurs

Bit 14 **NRST_SHDW:** Reset generation in Shutdown mode
0: Reset generated when entering the Shutdown mode
1: No reset generated when entering the Shutdown mode

Bit 13 **NRST_STDBY:** Reset generation in Standby mode
0: Reset generated when entering the Standby mode
1: No reset generate when entering the Standby mode

Bit 12 **NRST_STOP:** Reset generation in Stop mode
0: Reset generated when entering the Stop mode
1: No reset generated when entering the Stop mode

Bit 11 **BDRST_POR:** Backup domain reset with power-on reset
0: The backup domain is not reset after a V_{DD} domain brownout reset (BOR).
This configuration must be used when V_{BAT} supply source is different from V_{DD}.
1: The backup domain is reset after a V_{DD} domain brownout reset (BOR). This configuration must be used when the V_{BAT} and V_{DD} are connected together. It is forbidden when V_{BAT} supply source is different from V_{DD}.

Bits 10:8 **BOR_LEV[2:0]:** BOR reset level

This bitfield contains the V_{DD} supply level threshold that activates/releases the reset.
000: BOR level 0 (reset level threshold around 1.7 V)
001: BOR level 1 (reset level threshold around 2.0 V)
010: BOR level 2 (reset level threshold around 2.2 V)
011: BOR level 3 (reset level threshold around 2.5 V)
100: BOR level 4 (reset level threshold around 2.8 V)

Bits 7:0 **RDP[7:0]:** Readout protection level

0xAA: Level 0 (readout protection not active)
0x55: Level 0.5 (readout protection not active, only nonsecure debug access is possible).
Only available when TrustZone is active (TZEN = 1)
0xCC: Level 2 (chip readout protection active)
Others: Level 1 (memories readout protection active)

Note: Refer to Section 7.6.2: Readout protection (RDP) for more details.

7.10.15 FLASH nonsecure boot address 0 register (FLASH_BOOT0R)

Address offset: 0x44

Reset value: 0xXXXX XXXF

This register can not be written if OPTLOCK bit is set.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0x0800 007F
(option bytes are loaded with values from the flash memory at reset release)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADD[24:9]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADD[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw							

Bits 31:7 **ADD[24:0]**: Nonsecure boot base address 0

The nonsecure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. ADD option bytes are selected following the BOOT0 pin or NSWBOOT0 state.
Examples:
ADD[24:0] = 0x0100000: Boot from nonsecure flash memory (0x0800 0000)
ADD[24:0] = 0x017F1E0: Boot from system memory bootloader (0x0BF8 F000)
ADD[24:0] = 0x0400000: Boot from nonsecure SRAM1 on S-Bus (0x2000 0000)

Bits 6:0 Reserved, must be kept at reset value.

7.10.16 FLASH nonsecure boot address 1 register (FLASH_BOOT1R)

Address offset: 0x48

Reset value: 0xXXXX XXXF

This register can not be written if OPTLOCK bit is set.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0x0BF8 F07F

(option bytes are loaded with values from the flash memory at reset release)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADD[24:9]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADD[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw							

Bits 31:7 **ADD[24:0]**: nonsecure boot address 1

The nonsecure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. ADD option bytes are selected following the BOOT0 pin or nSWBOOT0 state.

Examples:

ADD[24:0] = 0x0100000: Boot from nonsecure flash memory (0x0800 0000)

ADD[24:0] = 0x017F1E0: Boot from system memory bootloader (0x0BF8 F000)

ADD[24:0] = 0x0400000: Boot from nonsecure SRAM1 on S-Bus (0x2000 0000)

Bits 6:0 Reserved, must be kept at reset value.

7.10.17 FLASH secure boot address 0 register (FLASH_SBOOT0R)

Address offset: 0x4C

Reset value: 0xXXXX XXXX

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0x0C00 007C

(option bytes are loaded with values from the flash memory at reset release)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADD[24:9]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

ADD[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	BOOT_LOCK
rw	rw	rw	rw	rw	rw	rw	rw	rw							rw

Bits 31:7 **ADD[24:0]**: Secure boot base address 0

The secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. This bits correspond to address [31:7] ADD option bytes are selected following the BOOT0 pin or NSWBOOT0 state.
Examples:
ADD[24:0] = 0x018 0000: Boot from secure flash memory (0x0C00 0000)
ADD[24:0] = 0x01F F000: Boot from RSS (0x0FF8 0000)
ADD[24:0] = 0x060 0000: Boot from secure SRAM1 on S-Bus (0x3000 0000)

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **BOOT_LOCK**: Boot lock

When set, the boot is always forced to base address value programmed in ADD[24:0] option bytes, whatever the boot selection option. When set, this bit can only be cleared when RDP is at level 0.

7.10.18 FLASH secure watermark1 register 1 (FLASH_SECWM1R1)

Address offset: 0x50

Reset value: 0xFFXX FFXX

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xFFFF FF80

(register bits are loaded with values from the flash memory at OBL. Reserved bits are read as 1.)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SECWM1_STRT[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **SECWM1_END[6:0]:** End page of first secure area
This bitfield contains the last page of the secure area in bank 1.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **SECWM1_STRT[6:0]:** Start page of first secure area
This bitfield contains the first page of the secure area in bank 1.

7.10.19 FLASH secure watermark1 register 2 (FLASH_SECWM1R2)

Address offset: 0x54

Reset value: 0xXXXX FFFF

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xB480 FFFF

(register bits are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 **HDP1EN[7:0]**: Hide protection first area enable
0xB4: No HDP area 1
others: HDP first area enabled

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **HDP1_END[6:0]**: End page of first hide protection area
This bitfield contains the last page of the HDP area in bank 1.

Bits 15:0 Reserved, must be kept at reset value.

7.10.20 FLASH WRP1 area A address register (FLASH_WRP1AR)

Address offset: 0x58

Reset value: 0xXFXX FFXX

This register can not be written if OPTLOCK bit is set.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xFF80 FFFF

(register bits are loaded with values from the flash memory at OBL. Reserved bits are read as 1)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

Bit 31 **UNLOCK**: Bank 1 WPR first area A unlock
0: WRP1A start and end pages locked
1: WRP1A start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **END[6:0]**: Bank 1 WPR first area A end page
This bitfield contains the last page of the first WPR area in bank 1.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **STRT[6:0]**: Bank 1 WPR first area A start page
This bitfield contains the first page of the first WPR area for bank 1.

7.10.21 FLASH WRP1 area B address register (FLASH_WRP1BR)

Address offset: 0x5C

Reset value: 0xXFXX FFXX

This register can not be written if OPTLOCK bit is set.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xFF80 FFFF

(register bits are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

Bit 31 **UNLOCK**: Bank 1 WPR second area B unlock
0: WRP1B start and end pages locked
1: WRP1B start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **END[6:0]**: Bank 1 WRP second area B end page
This bitfield contains the last page of the second WRP area in bank 1.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **STRT[6:0]**: Bank 1 WRP second area B start page
This bitfield contains the first page of the second WRP area for bank 1.

7.10.22 FLASH secure watermark2 register 1 (FLASH_SECWM2R1)

Address offset: 0x60

Reset value: 0xFFXX FFXX

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xFFFF FF80

(register bits are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **SECWM2_END[6:0]**: End page of second secure area
This bitfield contains the last page of the secure area in bank 2.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **SECWM2_STRT[6:0]**: Start page of second secure area
This bitfield contains the first page of the secure area in bank 2.

7.10.23 FLASH secure watermark2 register 2 (FLASH_SECWM2R2)

Address offset: 0x64

Reset value: 0xXXXX FFFF

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xB480 FFFF

(register bits are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

Bits 31:24 **HDP2EN[7:0]:** Hide protection second area enable
0xB4: No HDP area 2
others: HDP second area is enabled.

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **HDP2_END[6:0]**: End page of hide protection second area
This bitfield contains the last page of the HDP area in bank 2.

Bits 15:0 Reserved, must be kept at reset value.

7.10.24 FLASH WPR2 area A address register (FLASH_WRP2AR)

Address offset: 0x68

Reset value: 0xXFXX FFXX

This register can not be written if OPTLOCK bit is set.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xFF80 FFFF

(register bits are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

Bit 31 **UNLOCK**: Bank 2 WPR first area A unlock
0: WRP2A start and end pages locked
1: WRP2A start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **END[6:0]**: Bank 2 WPR first area A end page
This bitfield contains the last page of the first WRP area in bank 2.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **STRT[6:0]**: Bank 2 WPR first area A start page
This bitfield contains the first page of the first WRP area for bank 2.

7.10.25 FLASH WPR2 area B address register (FLASH_WRP2BR)

Address offset: 0x6C

Reset value: 0xXFXX FFXX

This register can not be written if OPTLOCK bit is set.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

ST production value: 0xFF80 FFFF

(register bits are loaded with values from the flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

Bit 31 **UNLOCK**: Bank 2 WPR second area B unlock
0: WRP2B start and end pages locked
1: WRP2B start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **END[6:0]**: Bank 2 WPR second area B end page
This bitfield contains the last page of the second WRP area in bank 2.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **STRT[6:0]**: Bank 2 WPR second area B start page
This bitfield contains the first page of the second WRP area for bank 2.

7.10.26 FLASH secure block based bank 1 register x (FLASH_SECBB1Rx)

Address offset: 0x80 + 0x4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

This register is secure. It can be written only by secure access. This register can be protected against unprivileged access (refer to *Table 63: FLASH_SECBByRx registers access when TrustZone is active (TZEN = 1)*).

Access: no wait state; word, half-word, and byte access

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECi:** Page secure/nonsecure attribution (i = 31 to 0)

Each bit is used to set one page security attribution in bank 1.

0: Page (32 * ({x} - 1) + {i}) in bank 1 not block-based secure

1: Page (32 * ({x} - 1) + {i}) in bank 1 block-based secure

7.10.27 FLASH secure block based bank 2 register x (FLASH_SECBB2Rx)

Address offset: 0xA0 + 0x4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

This register is secure. It can be written only by a secure access. This register can be protected against unprivileged access (refer to *Table 63: FLASH_SECBByRx registers access when TrustZone is active (TZEN = 1)*).

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECi:** Page secure/nonsecure attribution (i = 31 to 0)

Each bit is used to set one page security attribution in bank 2.

0: Page (32 * ({x} - 1) + {i}) in bank 2 not block-based secure

1: Page (32 * ({x} - 1) + {i}) in bank 2 block-based secure

7.10.28 FLASH secure HDP control register (FLASH_SECHDPCR)

Address offset: 0xC0

Reset value: 0xA3A3 A3A3

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HDP2EXT_ACCDIS[7:0]								HDP1EXT_ACCDIS[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HDP2_ACCDIS[7:0]								HDP1_ACCDIS[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **HDP2EXT_ACCDIS[7:0]:** HDP2 extension area access disable

Register access depends on its current value. Refer to *HDP extension area access* for the full conditions.

0xA3: Access to HDP2 extension area granted

0x5C: Access to HDP2 extension area and HDP2 area denied, but HDP2_EXT (in FLASH_HDPEXTR) increment allowed at any time. (SECWM2Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*).

Others: Access to HDP2 extension area and HDP2 area denied. Update of HDP2_EXT size is not possible anymore .(SECWM2Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*)

Bits 23:16 **HDP1EXT_ACCDIS[7:0]:** HDP1 extension area access disable

Register access depends on its current value. Refer to *HDP extension area access* for the full conditions.

0xA3: Access to HDP1 extension area granted

0x5C: Access to HDP1 extension area and HDP1 area denied, but HDP1_EXT (in FLASH_HDPEXTR) increment allowed at any time. (SECWM1Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*)

Others: Access to HDP1 extension area and HDP1 area denied. update of HDP1_EXT size is not possible anymore .(SECWM1Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*)

Bits 15:8 **HDP2_ACCDIS[7:0]:** HDP2 area access disable

When set to a value different than 0xA3, this bitfield cannot be modified except by a system reset.

0xA3: Access to HDP2 area granted

Others: Access to HDP2 area denied (SECWM2Ry option-byte modification blocked - refer to *Rules for modifying specific option bytes*). When HDP2_ACCDIS value is different than 0xA3, any write access to HDP2_ACCDIS is ignored.

Bits 7:0 **HDP1_ACCDIS[7:0]:** HDP1 area access disable

When set to a value different than 0xA3, this bitfield cannot be modified except by a system reset.

0xA3: Access to HDP1 area granted

Others: Access to HDP1 area denied (SECWM1Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*). When HDP1_ACCDIS value is different than 0xA3, any write access to HDP1_ACCDIS is ignored.

7.10.29 FLASH privilege configuration register (FLASH_PRIVCFGR)

Address offset: 0xC4

Reset value: 0x0000 0000

This register can be read by both privileged and unprivileged access. PRIV is a nonsecure bit. SPRIV is a secure bit.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PRIV**: Privileged protection for nonsecure registers

This bit can be read by both privileged or unprivileged, secure and nonsecure access. This bit can be written by a secure or nonsecure privileged access. A secure or nonsecure unprivileged write access on PRIV bit is ignored

0: Nonsecure FLASH registers can be read and written by privileged or unprivileged access.

1: Nonsecure FLASH registers can be read and written by privileged access only.

Bit 0 **SPRIV**: Privileged protection for secure registers

This bit can be accessed only when TrustZone is enabled (TZEN = 1). This bit can be read by both privileged or unprivileged, secure and nonsecure access. This bit can be written only by a secure privileged access. A nonsecure write access on SPRIV bit is ignored. A secure unprivileged write access on SPRIV bit is ignored.

0: Secure FLASH registers can be read and written by privileged or unprivileged access.

1: Secure FLASH registers can be read and written by privileged access only.

7.10.30 FLASH HDP extension register (FLASH_SECHDPEXTR)

Address offset: 0xC8

Reset value: 0x0000 0000

This register is secure. It can be read and written only by secure access. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP2_EXT[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_EXT[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HDP2_EXT[7:0]**: HDP area extension in 4-Kbyte pages in bank 2
The extension starts at page offset HDP2_END+1 if HDP2 area is enable (HDP2EN = 0xB4). Otherwise, it starts at page offset SECWM2_STRT.
Register access depends on HDP2EXT_ACCDIS value (Refer to *HDP extension area access* for the full conditions).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **HDP1_EXT[7:0]**: HDP area extension in 4-Kbyte pages in bank 1
The extension starts at page offset HDP1_END+1 if HDP1 area is enable (HDP1EN = 0xB4). Otherwise, it starts at page offset SECWM1_STRT.
Register access depends on HDP1EXT_ACCDIS value (refer to *HDP extension area access* for the full conditions.

7.10.31 FLASH privilege block based bank 1 register x (FLASH_PRIVBB1Rx)

Address offset: 0xD0 + 0x4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

This register is privileged. It can be read written only by a privileged access. This register can be protected against nonsecure access (refer to *Table 64: FLASH_PRIVBByRx registers access when TrustZone is active (TZEN = 1)*).

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRIV31	PRIV30	PRIV29	PRIV28	PRIV27	PRIV26	PRIV25	PRIV24	PRIV23	PRIV22	PRIV21	PRIV20	PRIV19	PRIV18	PRIV17	PRIV16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVi:** Page privileged/unprivileged attribution (i = 31 to 0)
Each bit is used to set one page privilege attribution in bank 1.
0: Page (32 * ({x} - 1) + {i}) in bank 1 accessible by unprivileged access
1: Page (32 * ({x} - 1) + {i}) in bank 1 only accessible by privileged access

7.10.32 FLASH privilege block based bank 2 register x (FLASH_PRIVBB2Rx)

Address offset: 0xF0 + 0x4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

This register is privilege. It can be read written only by a privileged access. This register can be protected against nonsecure access (refer to *Table 64: FLASH_PRIVBByRx registers access when TrustZone is active (TZEN = 1)*).

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVi:** Page privileged/unprivileged attribution (i = 31 to 0)
Each bit is used to set one page security attribution in bank 2.
0: Page (32 * ({x} - 1) + {i}) in bank 2 accessible by unprivileged access
1: Page (32 * ({x} - 1) + {i}) in bank 2 only accessible by privileged access

7.10.33 FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)

Address offset: 0x110

Reset value: 0x0000 0000

This register is nonsecure. It can be written by both secure and nonsecure access. This register is read as zero. This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR register.

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OEM1KEYCRC[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **OEM2KEYCRC[7:0]**: 8-bit OEM2KEY CRC

CRC is automatically computed by hardware while loading the OEM2KEYkey. The CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm $X_8 + X_2 + X + 1$ (according the convention). Source code is available in *OEM Key CRC source*.

Note: CRC information is updated each time FLASH OEM2KEY registers are written

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **OEM1KEYCRC[7:0]**: 8-bit OEMKEY1 CRC

CRC is automatically computed by hardware while loading the OEM1KEY key. The CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm $X_8 + X_2 + X + 1$ (according the convention). Source code is available in *OEM Key CRC source.*

Note: CRC information is updated each time FLASH OEM1KEY registers are written

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

8 Instruction cache (ICACHE)

8.1 ICACHE introduction

The instruction cache (ICACHE) is introduced on the C-AHB code bus of the Cortex®-M33 processor, to improve performance when fetching instructions and data from internal and external memories.

Some specific features, like dual master ports, hit-under-miss, and critical-word-first refill policy, result in close to zero-wait-state performance in most use cases.

8.2 ICACHE main features

The main features of ICACHE are listed below:

- Bus interface
  - One 32-bit AHB slave port, the execution port (input from Cortex®-M33 C-AHB code interface)
  - Two AHB master ports: master1 and master2 ports, with outputs to Fast and Slow buses of main AHB bus matrix, respectively
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master access: feature used to decouple the traffic according to targeted memory. For example, the ICACHE assigns fast traffic (addressing flash memories and SRAMs) to the AHB master1 port, and slow traffic (addressing external memories) to the AHB master2 port, thus preventing processor stalls on line refills from external memories. This allows ISR (interrupt service routine) fetching on internal flash memory to take place in parallel with a cache line refill from external memories.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, **w**, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Memory address remap
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the code region, for execution from the C-AHB code interface)
- Replacement and refill
  - pLRU-t (pseudo-least-recently-used, based on binary tree) replacement policy, algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls

  - Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)
- Performance counters

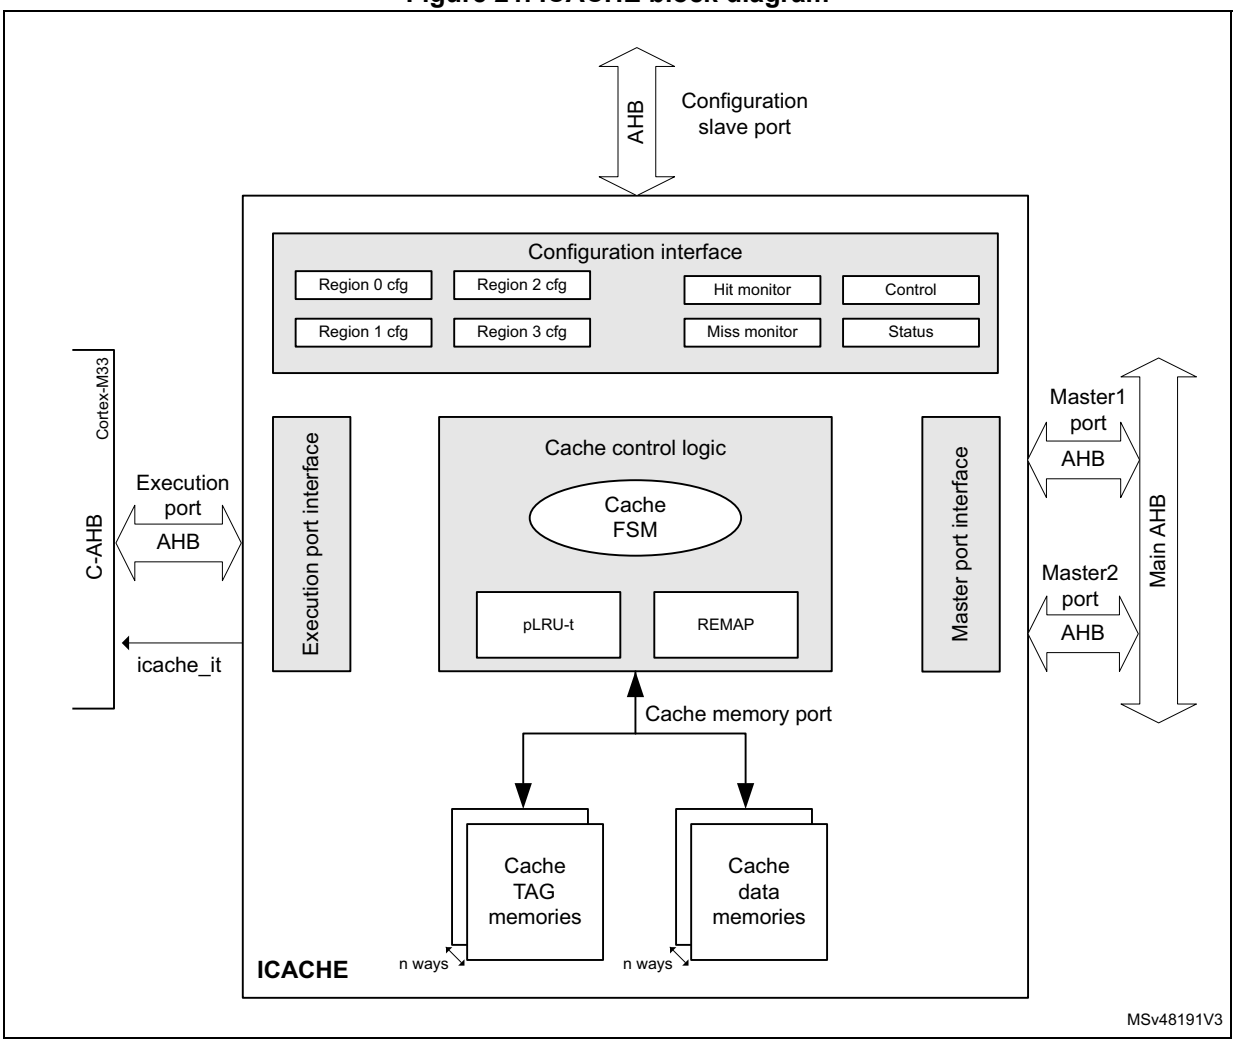
  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error, and optionally, to raise an interrupt
- TrustZone® security support
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, noninterruptible

8.3 ICACHE implementation

Table 68. ICACHE features

Feature	ICACHE
Number of ways	2
Cache size	8 Kbytes
Cache line width	16 bytes
Range granularity of memory regions to be remapped	2 Mbytes
Number of regions to remap	4
Data size of AHB slave interface	32 bits
Data size of AHB fast master1 interface	32 bits
Data size of AHB slow master2 interface	32 bits

8.4 ICACHE functional description



The purpose of this block is to cache instruction fetches or instruction memories loads, coming from the processor. As such, the ICACHE manages only cacheable read transactions, and does not manage cacheable write transactions.

The noncacheable transactions (both read and write) bypass the ICACHE.

For the error management purpose, if a write cacheable transaction is presented (this happens only in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

8.4.1 ICACHE block diagram

Figure 21. ICACHE block diagram

8.4.2 ICACHE reset and clocks

The ICACHE is clocked on the Cortex®-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (= 0).

Note: When disabled, the ICACHE is bypassed, except the remapping mechanism that is still functional: slave input requests (remapped or not) are forwarded to the master port(s).

8.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags indicating which data are contained in the cache data memories
- validity bits

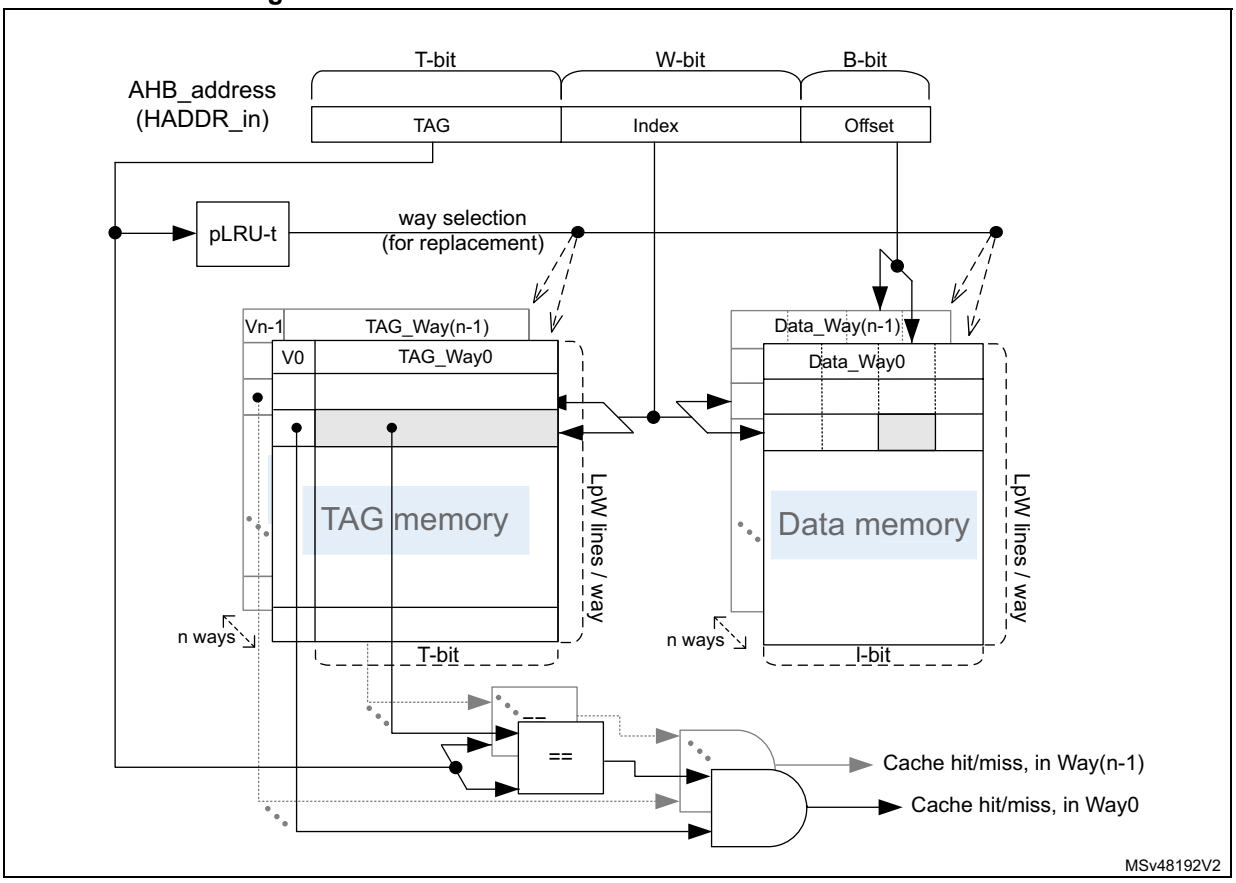
There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see *Table 69* for B and W definitions):



- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The following table gives a summary of the ICACHE main parameters for TAG memory dimensioning. *Figure 22* shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

Table 69. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 22. ICACHE TAG and data memories functional view

8.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The following table gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

Table 70. TAG memory dimensioning parameters for direct-mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, remapping, invalidation) remain the same in the direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 8.4.8*): only one way (the unique one) is possible for any data refill.

8.4.5 ICACHE enable

To activate the ICACHE, the EN bit in ICACHE_CR must be set to 1.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave to the master ports in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

To ensure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as noncacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether the ICACHE is enabled or not, if the input transaction address falls into the memory regions defined and enabled in ICACHE_CRRx (see *Figure 23*).

The ICACHE is, by default, disabled at boot.

8.4.6 Cacheable and noncacheable traffic

The ICACHE is developed for the Cortex®-M33 core. It is placed on the C-AHB bus, and thus caches the code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

To make other memory regions cacheable, the ICACHE supports a memory region remapping feature, used to define up to four external memory regions, whose addresses have an alias in the code region. Addressing these memory regions through their code alias address allows the memory request to be routed to the C-AHB bus, and to be managed by the ICACHE.

Any external memory space physically mapped at an address in the range [0x6000 0000:0xAFFF FFFF] can be aliased with an address in the range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the code region, the ICACHE implements the address remapping functionality first. If aliased, it is the remapped address, which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.

The remapping functionality is available also for noncacheable traffic, and when the cache is disabled.

Additional details on address remapping are provided in *Section 8.4.7*.

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 71*. This AHB attribute depends on the MPU (memory protection unit) programming for the addressed region.

Table 71. ICACHE cacheability for AHB transaction

AHB lookup attribute	Cacheability
1	Cacheable
0	Noncacheable

In the case of a noncacheable access (read or write), the ICACHE is bypassed. The AHB transaction is propagated unchanged to the master output port, except the transaction address, which may be modified due to the address remapping feature (see *Section 8.4.7*).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In the case of a cacheable access, the ICACHE behaves as explained in *Section 8.4.8*.

Cacheable memory regions are defined and programmed by the user in the MPU responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

Table 72 summarizes programmable configurations of various memories.

Table 72. Memory configurations

Memory	Cacheable (MPU programming)	Remapped in the ICACHE (ICACHE_CRRx programming)
Flash	Yes or no	Not required
SRAM	Not recommended	Not required
External memories	Yes	Required
	No	Required if the user wants code in external memories fetched on C-AHB bus (else on S-AHB bus)

8.4.7 Address remapping

The ICACHE allows an alias address to be defined in the code region for up to four external memory regions.

The address remapping is applied on the code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx (x = 0 to 3, number of remapped regions). This programming can be done only when the ICACHE is disabled.

Each region x can be individually enabled with REN in ICACHE_CRRx. Once enabled, the remap operation occurs even if the ICACHE is disabled, or if the transaction is noncacheable.

Remap regions can have different size: each can be programmed in RSIZE of its ICACHE_CRRx. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum of 2 Mbytes, and a maximum of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given code subregion base-address, and the modification of this address into its (remapped) physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code subregion base-address programmed in BASEADDR of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = $\log_2$ (region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region).
- If the region x is enabled, the master port output AHB address (HADDR_out) is composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs

Figure 23 describes the matching and the output address generation.

Figure 23. ICACHE remapping address mechanism

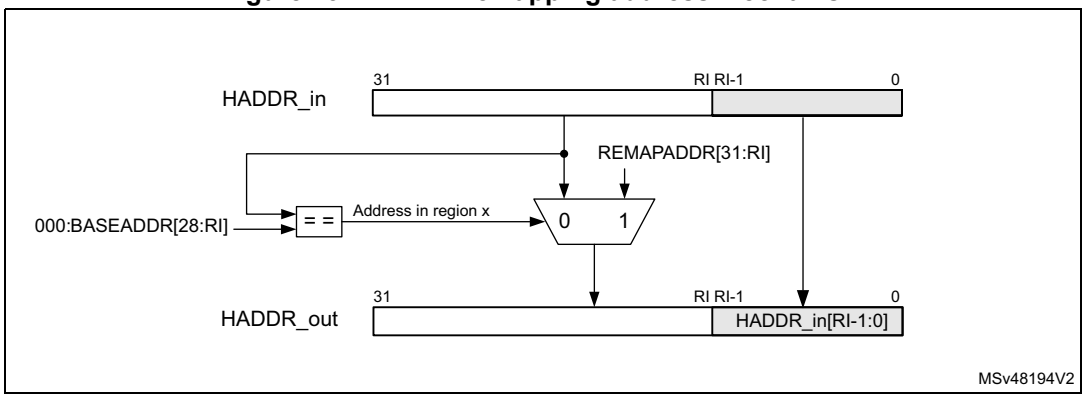


Table 73 summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending upon RSIZE.

Table 73. ICACHE remap region size, base address, and remap address

Region size (Mbytes)	Base address size (MSBs)	Remap address (MSBs)
2	8	11
4	7	10
8	6	9
16	5	8
32	4	7
64	3	6
128	2	5

Care must be taken while programming BASEADDR and REMAPADDR in ICACHE_CRRx: if the programmed value is bigger than expected (number of MSBs, see *Table 73*), the unneeded extra LSBs are ignored.

Typical remapping example: a 128-Mbyte external RAM region physically located in the external address range [0x9000 0000:0x97FF FFFF], remapped in the code section range [0x1800 0000:0x1FFF FFFF]:

- REMAPADDR[31:21] = 0x480
- BASEADDR[28:21] = 0xC0
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], while HADDR_in and BASEADDR[26:21] are ignored.

If the comparison matches:

- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst generated by the ICACHE master ports on the bus matrix (for cache line refill), by setting HBURST in ICACHE_CRRx with:

- WRAP for remapped external memories accessed through interfaces that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through the interfaces that do not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming the SAU (secure attribution unit) and the MPU (memory protection unit) attributes for both the external regions and their aliased code subregions.

8.4.8 Cacheable accesses

When the ICACHE receives a cacheable transaction from the Cortex®-M33, it checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy ensures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).

  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words) if no address remap occurs. If an address remap occurs, the kind of burst depends upon the HBURST programmed in corresponding ICACHE_CRRx.

  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port selected for the line refill.

- The address is not present in TAG memory, but belongs to the refill burst from the main memory currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache-line refill. The ICACHE can provide the requested data as soon as data are available at its master interface, thus avoiding a miss (fetching data from the main memory).

In the case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

8.4.9 Dual-master cache

The ICACHE implements a dual-port AHB master on the main AHB bus matrix: master1 and master2 ports. This is used to split the traffic going to different destination memories.

The nonremapped traffic goes systematically to master1 port. The remapped traffic can be routed on the master2 port by programming MSTSEL in ICACHE_CRRx (on a region basis).

The code can typically be fetched as follows:

- internal flash memory and internal SRAM on master1 port (Fast bus)
- external flash memory/RAM on master2 port (Slow bus)

For systems not implementing external memories, the traffic to the internal flash memory can be decoupled from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual-master feature allows the processor to have an alternative path in case of fetching from different memories.

8.4.10 ICACHE security

The ICACHE implements an Armv8-M TrustZone.

ICACHE configuration registers are protected at system level.

8.4.11 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in the ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished (all valid bits reset to 0), the ICACHE automatically clears BUSYF, and sets BSYENDF in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

8.4.12 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see *Section 8.4.8*).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.

  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

8.4.13 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

The code remapping at boot is not needed for a Cortex®-M33 as it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

8.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with lower performance profile (in terms of hit ratio) and stringent power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 22*). The power consumption is reduced by accessing, for each request, only the necessary cut of TAG and data memories. The cache effect still improves fetch performance, even if for most code execution, it is less efficient than with an n-way set associative cache mode.

8.6 ICACHE error management and interrupts

If an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

Table 74. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF in ICACHE_SR	ERRIE in ICACHE_IER	Set CERRF to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF in ICACHE_SR	BSYENDIE in ICACHE_IER	Set CBSYENDF to 1 in ICACHE_FCR

The ICACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from the master1 or master2 port back to the execution port.

8.7 ICACHE registers

8.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MISS MRST	HITM RST	MISS MEN	HITM EN
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAY SEL	CACHE INV	EN
													rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable
0: cache miss monitor switched off. Stopping the monitor does not reset it.
1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable
0: cache hit monitor switched off. Stopping the monitor does not reset it.
1: cache hit monitor enabled

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).
0: direct mapped cache (1-way cache)
1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

8.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRF	BSYENDF	BUSYF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
0: no error
1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
0: cache busy
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

8.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	BSYENDIE	Res.
													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)

0: interrupt disabled on error

1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end

Set by software to enable an interrupt generation at the end of a cache invalidate operation.

0: interrupt disabled on busy end

1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

8.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	CBSYENDF	Res.
													w	w	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CERRF**: clear cache error flag

Set by software.

0: no effect

1: clears ERRF flag in ICACHE_SR

Bit 1 **CBSYENDF**: clear busy end flag

Set by software.

0: no effect

1: clears BSYENDF flag in ICACHE_SR.

Bit 0 Reserved, must be kept at reset value.

8.7.5 ICACHE hit monitor register (ICACHE_HMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HITMON[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HITMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **HITMON[31:0]**: cache hit monitor counter

8.7.6 ICACHE miss monitor register (ICACHE_MMONR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MISSMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISSMON[15:0]**: cache miss monitor counter

8.7.7 ICACHE region x configuration register (ICACHE_CRRx)

Address offset: 0x020 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0200

Define an alias address in the code region for other regions, making them cacheable.

BASEDADDR and REMAPADDR fields are write locked (read only) when EN = 1 in ICACHE_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	MSTSEL	Res.	REMAPADDR[31:21]										
rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REN	Res.	Res.	Res.	RSIZE[2:0]			Res.	BASEADDR[28:21]							
rw				rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **HBURST**: output burst type for region x
0: WRAP
1: INCR

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **MSTSEL**: AHB cache master selection for region x
0: no action (master1 selected by default)
1: master2 selected

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **REMAPADDR[31:21]**: remapped address for region x
This field replaces the alias address defined by BASEADDR field.
The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15 **REN**: enable for region x
0: disabled
1: enabled

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:9 **RSIZE[2:0]**: size for region x
000: reserved
001: 2 Mbytes
010: 4 Mbytes
011: 8 Mbytes
100: 16 Mbytes
101: 32 Mbytes
110: 64 Mbytes
111: 128 Mbytes

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **BASEADDR[28:21]**: base address for region x
This alias address is replaced by REMAPADDR field.
The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

8.7.8 ICACHE register map

Table 75. ICACHE register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

9 Power control (PWR)

9.1 PWR introduction

The power controller manages all device power supplies and power modes transitions.

9.2 PWR main features

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domain (V_{CORE})
  - V_{DD} domain
  - Backup domain
  - Analog domain (V_{DDA})
  - Supply for the SMPS power stage (available on SMPS packages)
  - V_{DDIO2} domain on port PG[15:2]
  - V_{DDUSB} for USB transceiver
- System supply voltage regulation
  - SMPS step-down converter
  - Linear voltage regulator (LDO)
- Power supply supervision
  - BOR monitor
  - PVD monitor
  - PVM monitor (V_{DDA}, V_{DDUSB}, V_{DDIO2})
- Power management
  - Operating modes
  - Voltage scaling control
  - Low-power modes
- V_{BAT} battery charging
- TrustZone security and privileged protection

9.3 PWR functional description

9.3.1 PWR pins and internal signals

Table 76. PWR input/output pins

Pin name	Pin type	Description
VDD	Supply	Main supply
GND	Supply	Main ground
VDDA	Supply	Analog peripherals supply
VSSA	Supply	Analog peripherals ground

Table 76. PWR input/output pins (continued)

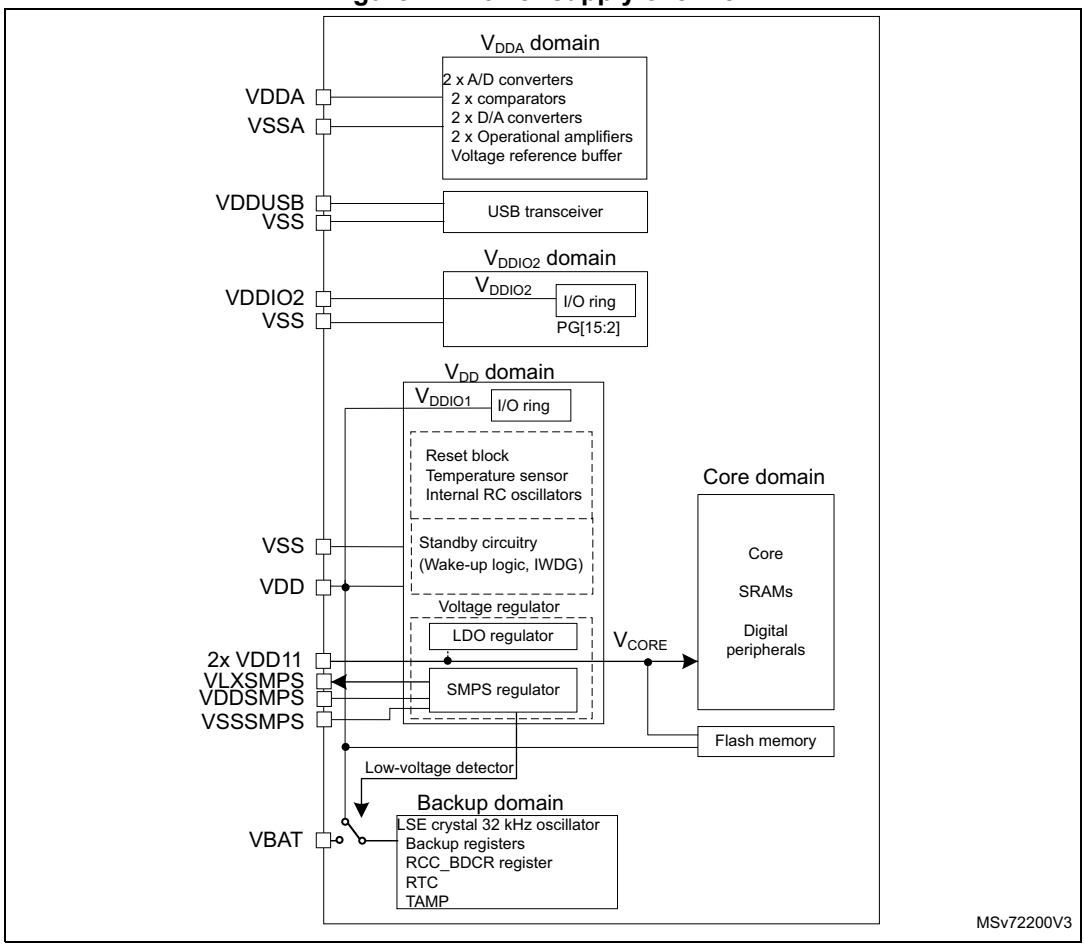
Pin name	Pin type	Description
VDDIO2	Supply	Independent I/O supply
VDDUSB	Supply	USB supply
VDD11 (packages with SMPS)/VCAP (packages without SMPS)	Supply	Logic supply (V_{CORE})
VBAT	Supply	Backup domain supply
VDDSMPS	Supply	SMPS supply
VSSSMPS	Supply	SMPS ground
VLXSMPS	Supply	SMPS output
VREF+	Supply	ADC/DAC high reference voltage
VREF-	Supply	ADC/DAC low reference voltage
WKUPx (x = 1 to 8)	Input	Wake-up pins
PWR_CSLEEP	Output	MCU in Sleep mode
PWR_CSTOP	Output	MCU in Stop mode

Table 77. PWR internal input/output signals

Internal signal name	Signal type	Description
WKUPx_y (x = 1 to 10, y = 1 to 4)	Input	Wake-up event source selection

Each of ten wake-up events WKUPx, (x = 1 to 10), can be generated from pins or internal events, selected by WUSELx[1:0] in PWR_WUCR3.

Table 78. PWR wake-up source selection



Wake-up event	Internal signal source (x = 1 to 8)			
	WKUPx_0 (WUSELx = 00)	WKUPx_1 (WUSELx = 01)	WKUPx_2 (WUSELx = 10)	WKUPx_3 (WUSELx = 11)
WKUP1	PA0	PB2	PE4	Reserved
WKUP2	PA4	PC13	PE5	Reserved

WKUP10	I3C2 reset pattern			

9.3.2 PWR power supplies and supply domains

Figure 24. Power supply overview

External power supplies

The devices require a 1.71 V to 3.6 V V_{DD} operating voltage supply. Several independent supplies can be provided for specific peripherals. Those supplies must not be provided without a valid operating supply on the VDD pin:

- V_{DD} = 1.71 V to 3.6 V (functionality guaranteed down to V_{BOR} minimum value)
  V_{DD} is the external power supply for the I/Os, the internal regulator and the system analog such as reset, power management and internal clocks. It is provided externally through the VDD pins.

- V_{DDA} = 1.58 V (COMPs) / 1.6 V (DACs, OPAMP) / 1.62 (ADCs) / 1.8 V (VREFBUF) to 3.6 V

  V_{DDA} is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The V_{DDA} voltage level is independent from the V_{DD} voltage and must be connected to VDD when these peripherals are not used.

- V_{DDSMPS} = 1.71 V to 3.6 V

  V_{DDSMPS} is the external power supply for the SMPS step-down converter. It is provided externally through VDDSMPS supply pin, and must be connected to the same supply as VDD pin when the SMPS is used in the application. When the SMPS is not used, it is recommended to connect both VDDSMPS and VLXSMPS to GND.

- V_{LXSMPS} is the SMPS step-down converter output.

  Note: The SMPS power supply pins are available only on a specific package with SMPS step-down converter option.

- V_{DDUSB} = 3.0 V to 3.6 V

  V_{DDUSB} is the external independent power supply for USB transceivers. The V_{DDUSB} voltage level is independent from the V_{DD} voltage and must preferably be connected to VDD when the USB is not used.

- V_{DDIO2} = 1.08 V to 3.6 V

  V_{DDIO2} is the external power supply for 14 I/Os (port G[15:2]). The V_{DDIO2} voltage level is independent from the V_{DD} voltage and must preferably be connected to VDD when PG[15:2] are not used.

- V_{BAT} = 1.65 V to 3.6 V (functionality guaranteed down to V_{BOR_VBAT} minimum value, refer to the product datasheet)

  V_{BAT} is the power supply when V_{DD} is not present (through power switch) for RTC, TAMP, external 32 kHz oscillator, and backup registers.

- V_{REF-}, V_{REF+}

  V_{REF+} is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

  V_{REF+} can be grounded when ADC and DAC are not active.

  The internal voltage reference buffer supports four output voltages, that are configured with VRS bit in the VREFBUF_CSR register:

  – V_{REF+} around 1.5 V. This requires $V_{DDA} \geq 1.8$ V.
  – V_{REF+} around 1.8 V. This requires $V_{DDA} \geq 2.1$ V.
  – V_{REF+} around 2.048 V. This requires $V_{DDA} \geq 2.4$ V.
  – V_{REF+} around 2.5 V. This requires $V_{DDA} \geq 2.8$ V.

  VREF- and VREF+ pins are not available on all packages. When not available, they are bonded to VSSA and VDDA, respectively.

  When the VREF+ is double-bonded with VDDA in a package, the internal voltage reference buffer is not available and must be kept disabled.

  V_{REF-} must always be equal to V_{SSA}.

Internal regulators

The devices embed two regulators: one LDO and one SMPS in parallel to provide the V_{CORE} supply for digital peripherals, SRAMs and embedded flash memory. The SMPS

generates this voltage on VDD11 (two pins) with a total external capacitor of 4.7 µF typical and requires an external coil of 2.2 µH typical.

The LDO generates this voltage on VCAP (one pin) with a total of external capacitor of 4.7 µF typical.

Both regulators can provide two different voltages (voltage scaling) and can operate in Stop mode.

It is possible to switch from SMPS to LDO and from LDO to SMPS on the fly.

Power-up and power-down power sequences

During power-up and power-down phases, the following power sequence requirements must be respected:

- When V_{DD} is below 1 V, other power supplies (V_{DDA}, V_{DDIO2}, V_{DDUSB}) must remain below V_{DD} + 300 mV.
- When V_{DD} is above 1 V, all power supplies are independent.

During the power-down phase, V_{DD} can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling capacitors to be discharged with different time constants during the power-down transient phase.

Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply that can be separately filtered and shielded from noise on the PCB:

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The V_{DDA} supply voltage can be different from V_{DD}. The presence of V_{DDA} must be checked before enabling any of the analog peripherals supplied by V_{DDA} (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

After reset, ADC and analog switch control supplied by V_{DDA} are logically and electrically isolated and therefore are not available. The isolation must be removed before using the analog peripherals, by setting the ASV bit in the PWR_SVMCR register, once the V_{DDA} supply is present.

The V_{DDA} supply can be monitored by the analog voltage monitors (AVM), and compared with two thresholds (1.6 V for AVM1 or 1.8 V for AVM2), refer to *Peripheral voltage monitoring (PVM)* for more details.

When a single supply is used, V_{DDA} can be externally connected to V_{DD} through the external filtering circuit in order to ensure a noise-free V_{DDA} reference voltage.

ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+, a separate reference voltage lower than V_{DDA}. V_{REF+} is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

V_{REF+} can be provided either by an external reference of by an internal buffered voltage reference (VREFBUF).

The internal voltage reference can output a configurable voltage: 1.5 V, 1.8 V, 2.048 V or 2.4 V. The internal voltage reference can also provide the voltage to external components through VREF+ pin. Refer to the device datasheet and to *Section 24.5.3: VREFBUF register map* for further information.

Independent I/O supply rail

Some I/Os from port G (PG[15:2]) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the VDDIO2 pin. The V_{DDIO2} voltage level is completely independent from V_{DD} or V_{DDA}. The VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by V_{DDIO2} are logically and electrically isolated and therefore are not available. The isolation must be removed before using any I/O from PG[15:2], by setting the IO2SV bit in PWR_SVMCR, once the V_{DDIO2} supply is present.

The V_{DDIO2} supply is monitored by the IO2 voltage monitoring (IO2VM) and compared with the internal reference voltage (3/4 VREFINT, around 0.9 V), refer to *Peripheral voltage monitoring (PVM)* for more details.

Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. V_{DDUSB} range is from 3.0 V to 3.6 V and is completely independent from V_{DD} or V_{DDA}. The VDDUSB pin is not available for some small packages. It is internally connected with V_{DD}. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the USB features supplied by V_{DDUSB} are logically and electrically isolated and therefore are not available. The isolation must be removed before using the USB peripheral, by setting the USV bit in PWR_SVMCR, once the V_{DDUSB} supply is present.

The V_{DDUSB} supply is monitored by the USB voltage monitoring (UVM) and compared with the internal reference voltage (V_{REFINT}, around 1.2 V), refer to *Peripheral voltage monitoring (PVM)* for more details.

Battery backup domain (also known as RTC domain)

To retain the content of the backup registers and supply the RTC and TAMP functions when V_{DD} is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The backup domain supply is V_{SW}, which is the output of a power switch between V_{DD} and V_{BAT}. The switch between V_{DD} and V_{BAT} supplies is automatically controlled by the brownout reset circuitry.

When V_{DD} is below the lowest brownout reset threshold (V_{BOR0}), the VBAT pin powers the RTC and TAMP peripherals, and LSE oscillators.

PC13, PC14 and PC15 pins, that can be configured by the RTC, the TAMP, or the LSE, are also powered by the VBAT pin.

When V_{DD} is higher than V_{BOR0}, the V_{DD} pin powers all previous functions.

Note: Due to the fact that the analog power switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the speed must be limited (refer to the datasheet for more details) and these I/Os must not be used as a current source (for example to drive a LED).

Caution: During $t_{RSTTEMPO}$ (temporization at V_{DD} startup) or after a PDR has been detected, the power switch between V_{BAT} and V_{DD} remains connected to V_{BAT}.

Caution: During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (refer to the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into V_{BAT} through an internal diode connected between V_{DD} and the power switch (V_{BAT}). If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

If no external battery is used in the application, it is recommended to connect V_{BAT} externally to V_{DD} with a 100 nF external ceramic decoupling capacitor.

Backup domain access

After a system reset, the backup domain (RCC_BDCR, RTC registers, TAMP registers and backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the RCC_AHB1ENR2.
2. Set the DBP bit in the PWR disable backup domain register (PWR_DBPR) to enable access to the backup domain.

VBAT battery charging

When V_{DD} is present, It is possible to charge the external battery on VBAT through an internal resistance.

The V_{BAT} charging is done either through a 5 kΩ resistor or through a 1.5 kΩ resistor depending on the VBRS bit value in PWR_BDCR.

The battery charging is enabled by setting VBE bit in PWR_BDCR. It is automatically disabled in V_{BAT} mode.

9.3.3 PWR system supply voltage regulation

SMPS and LDO embedded regulators

The devices embed two internal regulators, that can be selected when the application runs, depending on the application requirements:

- a SMPS step-down converter
- a linear voltage regulator (LDO)

The SMPS allows the power consumption to be reduced but some applications can be perturbed by the noise generated by the SMPS, requiring the application to switch to LDO.

The LDO and the SMPS regulators have two modes: Main regulator mode (used when performance is needed), and Low-power regulator mode. LDO or SMPS can be used in all voltage scaling ranges, and in all Stop modes.

LDO and SMPS versus reset, voltage scaling, and low-power modes

After reset, the regulator is the LDO, in range 2. Switching to SMPS provides lower consumption in particular at high V_{DD} voltage. It is possible to switch from LDO to SMPS, or from SMPS to LDO in any range, by configuring the REGSEL bit.

When exiting the Stop or Standby mode, the regulator is the same than when entering low-power modes. The voltage range is the range 2, except when exiting Stop 0 mode.

LDO and SMPS step-down converter fast startup

Note: After BOR reset, the LDO and SMPS regulators starts in slowstartup mode. This slowstartup feature is selected to limit the inrush current after power-on reset. This increases the wake-up time when exiting Stop or Standby mode.

However, it is possible to configure a faster startup on the fly and it is applied for next startup either after a system reset or wake-up from low-power mode except Shutdown and V_{BAT} modes. The fast startup is selected by setting the FSTEN bit in the PWR_CR3 register.

Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique that consists in increasing or decreasing the voltage used for the digital peripherals (V_{CORE}), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase V_{CORE} is known as overvolting. It allows the device to improve its performance.

Dynamic voltage scaling to decrease V_{CORE} is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

The regulator operates in the following ranges:

- Range 1: high performance

  It provides a typical output voltage at 0.9 V. It is used when the system clock frequency is up to 96 MHz.
- Range 2: low-power range

  It provides a typical output voltage at 0.75 V. The system clock frequency can be up to 48 MHz.

Voltage scaling is selected through the R1EN and R2EN bits in the PWR_VOSR register. The EPOD (embedded power distribution) booster must be enabled and ready before increasing the system clock frequency above 24 MHz in range 1 and range 2.

The sequence to switch the voltage scaling from range 2 (lower power) to range 1 (high performance) with system clock above 24 MHz is the following:

1. Configure the BOOSTSEL[1:0] and the BOOSTDIV[3:0] in the RCC_CFGR4 register to generate a booster clock frequency between 3 and 16 MHz.
2. Program R1EN = 1 and R2EN = 0 in the PWR_VOSR register.
3. Wait until the R1RDY flag is set in the PWR_VOSR register.
4. Set BOOSTEN in the PWR_VOSR register. This step can be done together with R1EN and R2EN programming
5. Wait until the BOOSTRDY flag is set in the PWR_VOSR register.
6. Adjust number of wait states according new frequency target in range 1 (LATENCY bits in the FLASH_ACR).
7. Configure and switch to new system frequency.

The sequence to switch the voltage scaling from range 1 (higher performance) to range 2 (lower power) is:

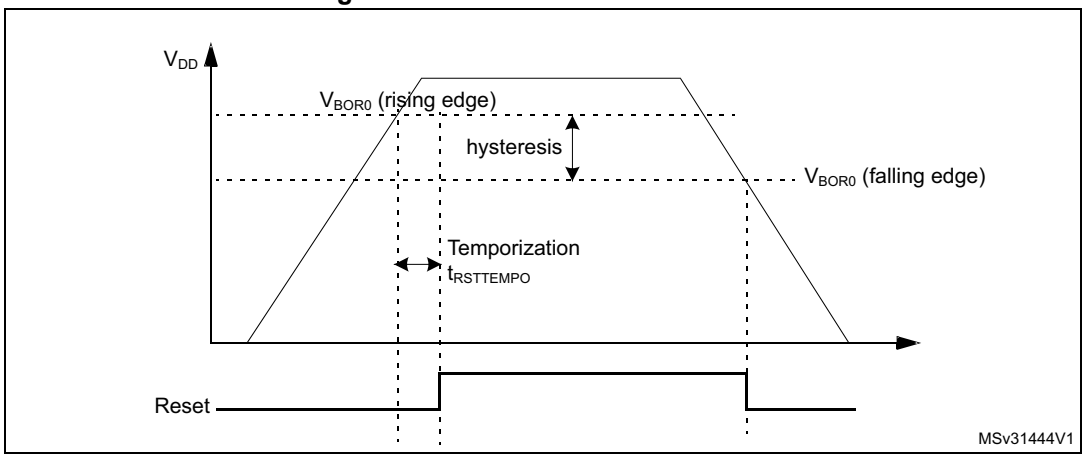
1. Reduce the system frequency to a value lower than 48 MHz.
2. Adjust number of wait states according new frequency target (LATENCY bits in the FLASH_ACR).
3. If new SYSCLK ≤ 24 MHz, clear BOOSTEN in the PWR_VOSR register.
4. Program R1EN = 0 and R2EN = 1 in the PWR_VOSR register. This step can be done together with BOOSTEN clearing.

Caution: The booster clock source must not be disabled when the booster is enabled.

9.3.4 PWR power supply supervision

Brownout reset (BOR)

The device has an integrated brownout reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.



Five BOR thresholds can be selected through option bytes. BOR0 provides the always enabled power-on/powerdown functionality, independent from any other higher BOR level selection.

During power-on, the BOR keeps the device under reset until the supply voltage V_{DD} reaches the specified VBORx threshold. When V_{DD} drops below the selected threshold, a device reset is generated. When V_{DD} is above the VBORx upper limit, the device reset is released and the system can start.

For more details on the brownout reset thresholds, refer to the electrical characteristics section in the datasheet.

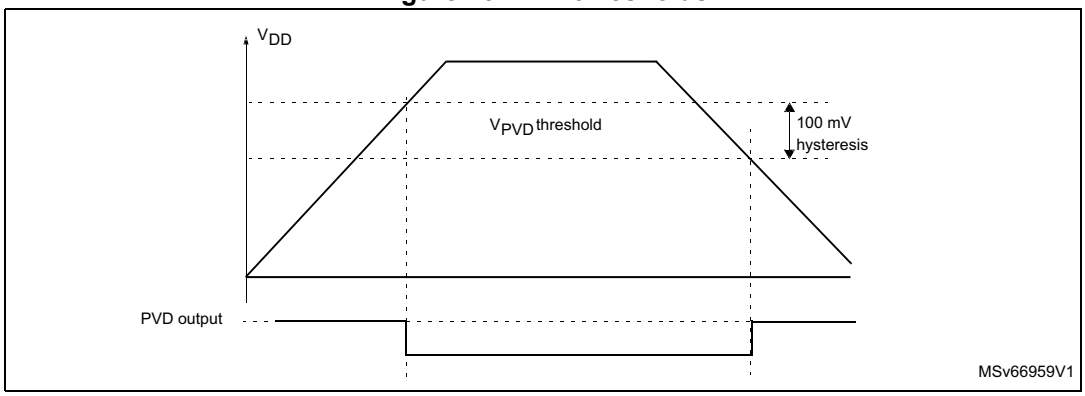
During Standby mode and if BOR level 0 is selected, it is possible to set the BOR in ultra-low-power mode to further reduce the current consumption by setting the ULPMEN bit in PWR control register 1 (PWR_CR1).

Figure 25. Brownout reset waveform

1. The reset temporization $t_{RSTTEMPO}$ is present only for the BOR lowest threshold (VBOR0).

Programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PVDLS[2:0] bits in the PWR supply voltage monitoring control register (PWR_SVMCR).



The PVD is enabled by setting the PVDE bit.

A PVDO flag is available in the PWR supply voltage monitoring control register (PWR_SVMCR) to indicate if V_{DD} is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers (refer to *Table 91: PWR interrupt requests*).

The rising/falling edge sensitivity of the EXTI Line must be configured according to PVD output behavior. For example, if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when V_{DD} drops below the PVD threshold. As an example, the service routine can perform emergency shutdown tasks.

The PVD can remain active in Stop 0, Stop 1, Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVD is not functional in Stop 3 mode.

Figure 26. PVD thresholds

Peripheral voltage monitoring (PVM)

Only V_{DD} is monitored by default, as it is the only supply required for all system-related functions. The other supplies (V_{DDA}, V_{DDIO2} and V_{DDUSB}) can be independent from V_{DD} and can be monitored with four peripheral voltage monitoring (PVM):

- The UVM monitors the USB supply V_{DDUSB}. VDDUSBRDY indicates if the V_{DDUSB} independent power supply is higher or lower than the V_{UVM} threshold.
- The IO2VM monitors the PG[15:2] supply V_{DDIO2}. VDDIO2RDY indicates if the V_{DDIO2} independent power supply is higher or lower than the VI_{O2VM} threshold.
- The AVM1 monitors the analog supply V_{DDA}. VDDA1RDY indicates if the V_{DDA} independent power supply is higher or lower than the V_{AVM1} threshold.
- The AVM2 monitors the analog supply V_{DDA}. VDDA2RDY indicates if the V_{DDA} independent power supply is higher or lower than the V_{AVM2} threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVMx output interrupt is generated when the independent power supply drops below the PVM threshold and/or when it rises above the PVM threshold, depending on EXTI line rising/falling edge configuration.

Refer to *Table 91: PWR interrupt requests*.

Each PVM can remain active in Stop 0, Stop 1, Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVM is not functional in Stop 3 mode.

The independent supplies (V_{DDA}, V_{DDIO2} and V_{DDUSB}) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies:

Table 79. PVM features

PVM	Power supply	PVM threshold
UVM	V_{DDUSB}	V_{UVM} (around 1.2 V)
IO2VM	V_{DDIO2}	V_{IO2VM} (around 0.9 V)
AVM1	V_{DDA}	V_{AVM1} (around 1.6 V)
AVM2	V_{DDA}	V_{AVM2} (around 1.8 V)

- If these supplies are shorted externally to V_{DD}, the application assumes they are available without enabling any peripheral voltage monitoring.
- If these supplies are independent from V_{DD}, the peripheral voltage monitoring (PVM) can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB peripheral:

1. If V_{DDUSB} is independent from V_{DD}:
   a) Enable the UVM by setting UVMEN bit in the PWR supply voltage monitoring control register (PWR_SVMCR).
   b) Wait for the UVM wake-up time.
   c) Wait until VDDUSBRDY bit is set in the PWR supply voltage monitoring status register (PWR_SVMSR).
   d) Disable the UVM for consumption saving (optional).
2. Set the USV bit in the PWR supply voltage monitoring control register (PWR_SVMCR) to remove the V_{DDUSB} power isolation.

The following sequence must be done before using any I/O from PG[15:2]:

1. If V_{DDIO2} is independent from V_{DD}:
   a) Enable the IO2VM by setting IO2VM bit in the PWR supply voltage monitoring control register (PWR_SVMCR).
   b) Wait for the IO2CVM wake-up time.
   c) Wait until VDDIO2RDY bit is set in the PWR supply voltage monitoring status register (PWR_SVMSR).
   d) Disable the IO2VM for consumption saving (optional).
2. Set the IO2SV bit in the PWR supply voltage monitoring control register (PWR_SVMCR) to remove the V_{DDIO2} power isolation.

The following sequence must be done before using any of these analog peripherals: analog to digital converters, digital to analog converters, comparators, operational amplifiers, voltage reference buffer:

1. If V_{DDA} is independent from V_{DD}:
   a) Enable the AVM1 or AVM2 by setting AVM1EN or AVM2EN bit in the PWR supply voltage monitoring control register (PWR_SVMCR).
   b) Wait for the AVM wake-up time.
   c) Wait until VDDA1RDY or VDDA2RDY bit is set in the PWR supply voltage monitoring status register (PWR_SVMSR).
   d) Disable the AVM for consumption saving (optional).
2. Set the ASV bit in the PWR supply voltage monitoring control register (PWR_SVMCR) to remove the V_{DDA} power isolation.

9.3.5 PWR power management

Power modes overview

By default, the microcontroller is in Run mode after a system or a power reset. Reducing power consumption in Run mode is done by configuring voltage scaling according to application performance needs. Refer to *Dynamic voltage scaling management*. Unused RAMs can definitively be powered-off with SRAM1PD or SRAM2PD bits in PWR_CR1. Once an SRAM has been powered off using this configuration bit, it cannot be powered on back again until the next power-on reset. Power consumption is also reduced by reducing SYSCLK, HCLK and PCLK clocks speed, or gating unused peripherals clocks. Refer to *Section 10: Reset and clock control (RCC)* for more details.

Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wake-up sources.

The device features these low-power modes:

- Sleep mode:

  CPU clock off, all peripherals including Cortex-M33 core such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs (refer to *Sleep mode*).
- Stop 0, Stop 1, Stop 2, Stop 3 modes:

Stop mode achieves the lowest power consumption while retaining the content of SRAM and registers. In Stop 0 and Stop 1, the SRAMs can be programmed, with the SRAMFWU bit of the PWR_CR2 register, to remain in normal run mode, to allow short wake-up time.

In Stop 1, Stop 2, and Stop3, the SRAMs can be totally or partially switched off, to further reduce consumption (refer to the xRAMyPDS bits of the PWR_CR2 register). When the SRAM is definitively powered down through PWR_CR1, the power-down in Stop mode configuration in the PWR_CR2 register for the same SRAM has no effect. All clocks in the core domain are stopped. The MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are disabled. The LSE or LSI is still running.

The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

Some peripherals are autonomous and can operate in Stop mode by requesting their kernel clock and their bus (APB or AHB) when needed, in order to transfer data with GPDMA1 depending on peripherals and power mode.

In Stop 0 mode, the regulator remains in main regulator mode, allowing a very fast wake-up time but with much higher consumption.

In Stop 1, the regulator is in low power mode, and the whole core domain is fully powered. All autonomous peripherals are functional.

In Stop 2 mode, most of the core domain (D1 domain) is put in a lower leakage mode, keeping registers retention, but without any possible functionality. The D2 domain, embedding APB3 peripherals, is kept fully powered, so those peripherals can be kept functional.

Stop 3 is the lowest power mode with full retention, but the functional peripherals and sources of wake-up are reduced to the same ones than in Standby mode.

The system clock when exiting from Stop mode can be either MSIS up to 48 MHz or HSI16, depending on software configuration.

In case the wake-up clock is MSIS at 48 MHz, the EPOD booster must be configured (BOOSTSEL[1:0] = 01 in RCC_CFGR4) and enabled (BOOSTEN = 1 in PWR_VOSR) before entering Stop mode. Refer to System clock (SYSCLK) selection for more details.

Refer to *Stop 0 mode*, *Stop 1 mode*, *Stop 2 mode*, and *Stop 3 mode*.

- Standby mode:

  The Standby mode is used to achieve the lowest power consumption with BOR. The internal regulator is switched off so that the core domain is powered off. The MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are also switched off.

  The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

  The brownout reset (BOR) always remains active in Standby mode.

  The state of each I/O during Standby mode can be selected by software: I/O with internal pull-up, internal pulldown or floating.

  After entering Standby mode, SRAMs and register contents are lost except for registers in the backup domain and Standby circuitry. Optionally, the full SRAM2 or 8 Kbytes or 24 Kbytes or 32 Kbytes can be retained in Standby mode, supplied by the low-power regulator (standby with SRAM2 retention mode).

  The BOR can be configured in ultra-low-power mode to further reduce power consumption during standby mode and when the lowest threshold is selected (VBOR0).

  The device exits Standby mode when an external reset (NRST pin), an IWDG early wake-up event or reset, WKUP pin event (configurable rising or falling edge), a RTC event occurs (alarm, periodic wake-up, timestamp), a tamper detection or a I3C reset pattern detection.

  The system clock after wake-up is MSIS up to 12 MHz.

  Refer to *Standby mode*.

- Shutdown mode:

  The Shutdown mode allows the lowest power consumption. The internal regulator is switched off so that the core domain is powered off. The HSI16, the MSI (MSIS and MSIK), the LSI and the HSE oscillators are also switched off.

  The RTC can remain active (Shutdown mode with RTC, Shutdown mode without RTC).

  The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to backup domain is not supported.

  SRAMs and register contents are lost except for registers in the backup domain.

  The device exits Shutdown mode when an external reset (NRST pin), a WKUP pin event (configurable rising or falling edge), or a RTC event occurs (alarm, periodic wake-up, timestamp), a tamper detection or a I3C reset pattern detection.

  The system clock after wake-up is MSIS at 12 MHz.

  Refer to *Shutdown mode*.

The table below shows the power modes overview.

Table 80. Low-power mode summary

<table>
<tr><th>Mode name</th><th>Entry</th><th>Wake-up source(1)</th><th>Wake-up system clock</th><th>Effect on clocks</th><th>Voltage regulators</th></tr>
<tr><td rowspan="2">Sleep
(Sleep-now or Sleep-on-exit)</td><td>WFI or Return from ISR</td><td>Any interrupt</td><td rowspan="2">Same as before entering Sleep mode</td><td rowspan="2">CPU clock OFF

Table 81. Functionalities depending on the working mode(1) (continued)

Peripheral	Run	Sleep	Stop 0/1		Stop 2		Stop 3		Standby		Shutdown		VBAT
			-	Wake-up capability	-	Wake-up capability	-	Wake-up capability	-	Wake-up capability	-	Wake-up capability	
CRC calculation unit	O	O	-	-	-	-	-	-	-	-	-	-	-
GPIOs	O	O	O	O	O	O	(21)	22	(21)	22	(22)	22	-

1. Y = yes (enable). O = optional (disable by default, can be enabled by software). - = not available.
2. The flash banks can be configured in power-down mode. By default, they are not in power-down mode.
3. Flash can be accessed by GPDMA1 in Stop 0, Stop 1 and Stop 2 modes. ECC error interrupt or NMI wakes up from these Stop modes.
4. The SRAMs can definitively be powered off independently until the next device power on reset.
5. The SRAM clock can be gated on or off independently.
6. Sub-blocks of SRAM1 and SRAM2 can be powered-off in Stop 1, Stop 2, and Stop 3, to save power. SRAM1 and SRAM2 can be accessed by GPDMA1 in Stop 0, Stop 1 and Stop 2 modes.
7. Parity error interrupt or NMI wakes up from Stop mode.
8. Content of 32 Kbyte, 24 Kbyte, and/or 8 Kbyte block can be preserved.
9. Illegal access interrupt wakes up from Stop 0, 1, 2 modes.
10. GPDMA1 transfers are functional and autonomous in Stop 0 and 1 mode. Interrupts wake up from these Stop modes.
11. In Stop 2 mode, GPDMA1 supports only LPUART1, I2C3, LPTIM1, LPTIM3 and LPTIM4 requests. None of GPDMA1 triggers are supported. Interrupts wake up from Stop 2 modes.
12. Some peripherals with autonomous mode and wake-up from Stop capability can request HSI16, MSIS or MSIK to be enabled. In this case, the oscillator is woken up by the peripheral, and is automatically put off when no peripheral needs it.
13. USART and LPUART reception and transmission is functional and autonomous in Stop mode, in asynchronous and in SPI master modes. Interrupts wake up from Stop mode.
14. I2C reception and transmission is functional and autonomous in Stop mode. Interrupts wake up from Stop mode.
15. I3C reception and transmission, in controller and target modes, is functional and autonomous in Stop mode. Interrupts wake up from Stop mode.
16. I3C reset pattern detection wakes up from Stop 2, Stop 3, Standby and Shutdown modes. I3C pull-ups can be applied in Stop and Standby modes.
17. SPI reception and transmission is functional and autonomous in Stop mode. Interrupts wake up from Stop mode.
18. DAC1 (2 channels) conversion in sample and hold mode is functional and autonomous in Stop mode.
19. LPTIM is functional and autonomous in Stop mode.Interrupts wake up from Stop mode.
20. ADF is functional and autonomous in Stop mode. Interrupts wake up from Stop mode.
21. I/Os can be configured with internal pull-up, pull-down or floating in Stop 3 and Standby mode.
22. I/Os can be configured with internal pull-up, pull-down or floating in Shutdown mode but the configuration is lost when exiting the Shutdown mode.

Autonomous peripherals

Several peripherals support the autonomous mode which allows it to be functional and perform DMA transfers in Stop 0, Stop 1, and Stop 2 modes. Their interrupts wake up from Stop mode.

In Stop 0 and Stop 1 modes, the autonomous peripherals are DAC1 (2 channels), LPTIMx (x = 1 to 4), U(S)ARTx (x = 1, 3 to 5), LPUART1, SPIx (x = 1 to 3), I2Cx (x = 1 to 3), I3Cx (x = 1 to 2), ADF1, and GPDMA1.

In Stop 2 mode, the autonomous peripherals are LPTIM1, LPTIM3, LPTIM4, LPUART1, and I2C3. If one of these peripherals requests the AHB/APB clocks for a DMA transfer, the whole core domain is switched to Stop 1 higher leakage mode and the clock is distributed to GPDMA1, enabled SRAMs and peripherals in order to perform the autonomous peripheral DMA transfer. Then the core domain automatically returns to Stop 2 lower leakage mode.

Note: Only DMA requests from LPTIM1, LPTIM3, LPTIM4, LPUART1, or I2C3 peripherals are supported in Stop 2 mode. It is not possible to trig a GPDMA1 transfer in Stop 2 mode using GPDMA1 hardware triggers signals, even from those peripherals.

Low-power modes

Entering a low-power mode

The MCU enters low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex-M33 system control register is set on Return from ISR.

Entering a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Caution: The peripherals with autonomous mode feature are able to generate an AHB or APB clock request, depending on their internal events. If a clock request is present when WFI or WFE is executed, the low-power mode entry is delayed until the clock request is released.

Exiting a low-power mode

The way the MCU exits the Sleep or Stop mode depends on the way the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wake-up event can be generated either by:
  - an NVIC IRQ peripheral interrupt:
    When SEVONPEND = 0 in the Cortex-M33 system control register: By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC IRQ peripheral channel pending bit (in the NVIC interrupt clear pending register) must be cleared. Only NVIC interrupts with high enough priority wake up and interrupt the MCU.
    When SEVONPEND = 1 in the Cortex-M33 system control register: By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC IRQ peripheral channel pending bit (in the NVIC interrupt clear pending register) must be cleared. All NVIC interrupts wake up the MCU, even the disabled ones. Only enabled NVIC interrupts with high enough priority wake up and interrupt the MCU.
  - an event: by configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the

NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

After waking up from Standby or Shutdown mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).

Caution: When the device is in Stop mode, a peripheral interrupt powers on an internal oscillator. The corresponding NVIC interrupt channel must be enabled to allow the interrupt to exit the device from Stop mode. It is not allowed to disable a peripheral interrupt by disabling only the NVIC channel while keeping the peripheral interrupt enable, as the device could remain in Stop mode with clock ON.

Caution: The peripherals with autonomous mode feature are able to generate an AHB or APB clock request when the device is in Stop mode, depending on their internal events. The software must ensure that either DMA transfer or interrupt is served, by configuring properly and in a consistent way the RCC, the autonomous peripherals, the DMA channels and NVIC. Note that when an autonomous peripheral requests the bus clock in Stop mode, the AHB and APB clocks are distributed to all enabled peripherals. Consequently, enabled peripherals, even without autonomous mode capability, are temporarily clocked and can also generate an interrupt during this time. These peripherals interrupts wake up the device from Stop mode.

Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering Sleep mode

The MCU enters the Sleep mode as described in *Entering a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is clear (see the table below for details on how to enter the Sleep mode).

Exiting Sleep mode

The MCU exits the Sleep mode as described in *Exiting a low-power mode* (see the table below for details on how to exit the Sleep mode).

Table 82. Sleep mode

Sleep mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP = 0 – No interrupt (for WFI) or event (for WFE) pending Refer to the Cortex-M33 system control register.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 – No interrupt pending Refer to the Cortex-M33 system control register.

Table 82. Sleep mode (continued)

Sleep mode	Description
Mode exit	If WFI or Return from ISR was used for entry Interrupt (refer to *Table 128: STM32U3 series vector table*) If WFE was used for entry and SEVONPEND = 0: Wake-up event (refer to *Section 17.3: EXTI functional description*) If WFE was used for entry and SEVONPEND = 1: Interrupt even when disabled in NVIC (refer to *Table 128: STM32U3 series vector table*) or wake-up event (refer to *Section 17.3: EXTI functional description*)
Wake-up latency	None

Stop 0 mode

The Stop 0 mode is based on the Cortex-M33 Deepsleep mode combined with the peripheral clock gating. The voltage regulator is configured in main regulator mode. The MSIS, MSIK, HSI16 and HSE oscillators are disabled by hardware. The LSE and LSI are kept enabled if they were before entering Stop 0 mode.

Some peripherals with the autonomous mode capability can switch on HSI16 or MSIS or MSIK for transferring data (see *Autonomous peripherals* for details).

All SRAMs and register contents are preserved. SRAMs can be kept in normal mode to allow fast wake-up at a cost of extra power consumption.

The BOR is always available in Stop 0 mode.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering Stop 0 mode

The MCU enters the Stop 0 mode as described in *Entering a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 83* for details on how to enter the Stop 0 mode).

If the flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it cannot be stopped except by a reset (see Section 10.3 PWR functional description).
- The real-time clock (RTC) and tamper (TAMP) kernel clock is enabled by the RTCEN bit in RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_CSR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

Several peripherals can be autonomous in Stop 0 mode and can add consumption if they are enabled (see *Autonomous peripherals* for more details).

The OPAMPs, the COMPs, the DAC1 (two channels), the VREFBUF, the PVM, and the PVD can be used in Stop 0 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 2) and the temperature sensor can consume power during the Stop 0 mode, unless they are disabled before entering this mode.

Exiting Stop 0 mode

The MCU exits the Stop 0 mode as described in *Exiting a low-power mode* (see *Table 83* for details on how to exit Stop 0 mode).

When exiting Stop 0 mode by issuing an interrupt or a wake-up event, HSI16 is selected as system clock if the bit STOPWUCK is set in RCC_CFGR1. The MSIS oscillator is selected as system clock if STOPWUCK is cleared. The MSIS selection allows a wake-up at higher frequency (up to 48 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wake-up from Stop capability.

All peripheral clocks must be enabled to allow a wake-up from Stop interrupt (Refer to RCC for more details).

When exiting the Stop 0 mode, the MCU is in Run mode (Range 1 or Range 2 depending on regulator range configuration).

Table 83. Stop 0 mode

Stop 0 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 000 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 000 in PWR_CR1
	To enter Stop 0 mode, all EXTI line pending bits and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop 0 mode entry procedure is ignored and the program execution continues.

Table 83. Stop 0 mode (continued)

Stop 0 mode	Description
Mode exit	If WFI or Return from ISR was used for entry: – any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (refer to *Table 128: STM32U3 series vector table*). – any PWR wake-up line interrupt (WUF). The interrupt source can be WKUP pins or I3C reset pattern detection. – RTC, TAMP, IWDG or any other peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: – any EXTI line configured in event mode (refer to *Section 17.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: – any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (refer to *Table 128: STM32U3 series vector table*). – any EXTI line configured in event mode (refer to *Section 17.3: EXTI functional description*). – any PWR wake-up line interrupt (WUF). The interrupt source can be WKUP pins or I3C reset pattern detection. – RTC, TAMP, IWDG or any other peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request
	All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN, [PERIPH]SLPEN and [PERIPH]STPEN bits must be set in the RCC, and a functional independent clock must be selected).
Wake-up latency	Wake-up on flash: – HSI as SYSCLK: HSI setup + flash setup – MSI as SYSCLK: HSI setup + flash setup + MSI setup

Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the regulator is in low-power mode and the SRAMs can be totally or partially switched off to further reduce consumption (see the following table for details on how to enter and exit Stop 1 mode).

Table 84. Stop 1 mode

Stop 0 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 000 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 000 in PWR_CR1
	To enter Stop 0 mode, all EXTI line pending bits and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop 0 mode entry procedure is ignored and the program execution continues.
Mode exit	If WFI or Return from ISR was used for entry: – any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (refer to *Table 128: STM32U3 series vector table*). – any PWR wake-up line interrupt (WUF). The interrupt source can be WKUP pins or I3C reset pattern detection. – RTC, TAMP, IWDG or any other peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: – any EXTI line configured in event mode (refer to *Section 17.3: EXTI functional description*).). If WFE was used for entry and SEVONPEND = 1: – any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (refer to *Table 128: STM32U3 series vector table*). – any EXTI line configured in event mode (refer to *Section 17.3: EXTI functional description*) – any PWR wake-up line interrupt (WUF). The interrupt source can be WKUP pins or I3C reset pattern detection. – RTC, TAMP, IWDG or any other peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request
	All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN, [PERIPH]SLPEN and [PERIPH]STPEN bits must be set in the RCC, and a functional independent clock must be selected).
Wake-up latency	Wake-up on flash: – HSI as SYSCLK: HSI setup + flash setup – MSI as SYSCLK: HSI setup + flash setup + MSI setup

Stop 2 mode

The Stop 2 mode is similar to Stop 1 except that most of the core domain (D1 domain) is put in a lower leakage mode. Only the part of the core domain embedding APB3 peripherals (D2 domain) remains fully powered, allowing those peripherals to be functional.

The APB3 peripherals with the autonomous mode capability can switch on HSI16 or MSIS or MSIK for transferring data (see *Autonomous peripherals* for details).

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 2 mode.

I/O states in Stop 2 mode

In the Stop 2 mode, all I/O pins keep the same state as in the Run mode; except for I3C specific pull-up. PWR I3C pull-up control register 1 or 2 must be configured before entering Stop 2 mode in order to apply I3C pull-ups on corresponding I/Os. The I3C pull-up control bits must be cleared after exiting Stop 2 mode, to let I3C peripheral controls I/O pull-up activation.

Entering Stop 2 mode

The MCU enters the Stop 2 mode as described in *Entering a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 85* for details on how to enter the Stop 2 mode).

If the flash memory programming is ongoing, the Stop 2 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 2 mode entry is delayed until the APB access is finished.

In Stop 2 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 9.3: PWR functional description*).
- The real-time clock (RTC) and Tamper (TAMP) kernel clock is enabled by the RTCEN bit in the RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_CSR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.
- The I3Cx (x = 1, 2) reset pattern detection are enabled by the WUPEN9 and WUPEN10 bits in PWR_WUCR1.

Several peripherals can be autonomous in Stop 2 mode and can add consumption if they are enabled (see *Autonomous peripherals* for more details).

The COMPs, the PVM and the PVD can be used in Stop 2 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 2), the DAC1 (two channels), the temperature sensor, the OPAMP and the VREFBUF can consume power during the Stop 2 mode, unless they are disabled before entering this mode.

Caution: All the peripherals that cannot be functional in Stop 2 mode must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring the RCC registers.

Exiting Stop 2 mode

The MCU exits the Stop 2 mode as defined in *Exiting a low-power mode* (see *Table 85* for details on how to exit Stop 2 mode).

When exiting Stop 2 mode by issuing an interrupt or a wake-up event, HSI16 is selected as system clock if the bit STOPWUCK is set in RCC_CFGR1. MSIS is selected as system clock if STOPWUCK is cleared. The MSI selection allows a wake-up at higher frequency (up to 48 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wake-up from Stop capability.

All peripheral clocks must be enabled to allow a wake-up from Stop interrupt (Refer to Reset and clock control (RCC) for more details).

When exiting the Stop 2 mode, the MCU is in Run mode, range 2.

Table 85. Stop 2 mode

Stop 2 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 010 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 010 in PWR_CR1
	To enter Stop 2 mode, all EXTI line pending bits and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop mode entry procedure is ignored and the program execution continues.

Table 85. Stop 2 mode (continued)

Stop 2 mode	Description
Mode exit	If WFI or Return from ISR was used for entry: – any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (refer to *Table 128: STM32U3 series vector table*). – any PWR wake-up line interrupt (WUF). The interrupt source can be WKUP pins or I3C reset pattern detection. – RTC, TAMP, IWDG or any other peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: – any EXTI line configured in event mode (refer to *Section 17.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: – any EXTI line configured in interrupt mode (even if the corresponding EXTI Interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (refer to *Table 128: STM32U3 series vector table*). – any EXTI line configured in event mode (refer to *Section 17.3: EXTI functional description*) – any PWR wake-up line interrupt (WUF). The interrupt source can be WKUP pins or I3C reset pattern detection. – RTC, TAMP, IWDG or any other any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request
	All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN, [PERIPH]SLPEN and [PERIPH]STPEN bits must be set in the RCC, and a functional independent clock must be selected).
Wake-up latency	Wake-up on flash: – HSI as SYSCLK: regulator setup from low-power + D1 EPOD setup + HSI setup + flash setup – MSI as SYSCLK: regulator setup from low-power + D1 EPOD setup + HSI setup + flash setup + MSI setup

Stop 3 mode

The Stop 3 mode is based on the Cortex-M33 Deepsleep mode combined with peripheral clock gating. In Stop 3 mode, all clocks in the core domain are stopped. The MSIS, MSIK, HSI16 and HSE oscillators are disabled.

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduce consumption.

The BOR is always available in Stop 3 mode.

I/O states in Stop 3 mode

In the Stop 3 mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pulldown configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O. After wakeup from Stop 3 mode, the pull-up/pull-down I/O configuration remains retained based on PWR_PUCRx/PWR_PDCRx as long as APC bit is set.

Some I/Os (listed in *Section 12: General-purpose I/Os (GPIO)*) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Stop 3 mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

I3C specific pull-ups are activated thanks to PWR I3C pull-up control registers 1 or 2. These registers must be configured before entering Stop 3 mode in order to apply I3C pull-ups on corresponding I/Os. The I3C pull-up control bits must be cleared after exiting Stop 3 mode, to let I3C peripheral controls I/O pull-up activation.

The RTC outputs on PC13 and PB2 are functional in Stop 3 mode. The 22 wake-up pins multiplexed on eight events (WKUPx, x = 1 to 8).

Entering Stop 3 mode

The MCU enters the Stop 3 mode as described in *Entering a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 System Control register is set (see *Table 86* for details on how to enter the Stop 3 mode).

If the flash memory programming is ongoing, the Stop 3 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 3 mode entry is delayed until the APB access is finished.

In Stop 3 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 9.3: PWR functional description*).
- The real-time clock (RTC) and Tamper (TAMP) kernel clock is enabled by the RTCEN bit in the RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.
- The I3Cx (x = 1, 2) reset pattern detection are enabled by the WUPEN9 and WUPEN10 bits in PWR_WUCR1.

Exiting Stop 3 mode

The MCU exits the Stop 3 mode as described in *Exiting a low-power mode* (see *Table 86* for details on how to exit Stop 3 mode).

When exiting Stop 3 mode by issuing an interrupt or a wake-up event, HSI16 is selected as system clock if the bit STOPWUCK is set in RCC_CFGR1. MSIS is selected as system clock if STOPWUCK is cleared. The MSI selection allows a wake-up at higher frequency (up to 48 MHz).

When exiting the Stop 3 mode, the MCU is in Run mode, range 2.

When exiting Stop 3 mode, I/Os that were configured with pull-up or pull-down during Stop 3 through PWR_PUCRx or PWR_PDCRx, keep this configuration upon exiting Stop 3 mode until the APC bit in PWR_CR3 is cleared by software. Once APC is cleared, the I/Os pull-up/pull-down state is configured according to the GPIOx_PUPDR registers. The content of

the PWR_PUCRx or PWR_PDCRx registers is not lost and can be re-used for a sub-sequent entering into Stop 3 mode.

Figure 27. I/O states in Stop 3 mode

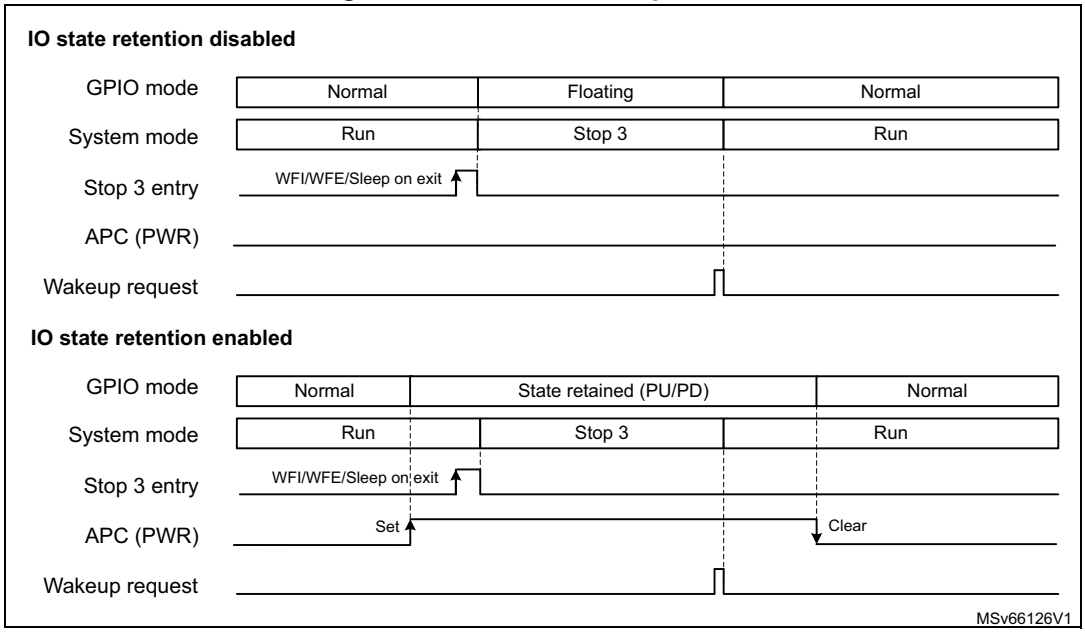

Table 86. Stop 3 mode

Stop 3 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 011 in PWR_CR1 – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 011 in PWR_CR1 – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wake-up source, cleared
	To enter Stop 3 mode, all WUFx, and the RTC/TAMP flags generating wake-up interrupts must be cleared. Otherwise, the Stop 3 mode entry procedure is completed but the Stop 3 is exited immediately after entry.

Table 86. Stop 3 mode (continued)

Stop 3 mode	Description
Mode exit	– Any PWR wake-up line interrupt (WUF). The wake-up line source can be WKUP pins edge, RTC or TAMP event, IWDG early wake-up or I3C reset pattern detection. – NRST pin external reset – BOR reset – IWDG reset
Wake-up latency	wake-up on flash: – HSI as SYSCLK: regulator setup from low-power + D1 EPOD setup + D2 EPOD setup + HSI setup + flash setup – MSI as SYSCLK: regulator setup from low-power + D1 EPOD setup + D2 EPOD setup + HSI setup + flash setup + MSI setup

Standby mode

The lowest power mode in which the BOR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the backup domain and Standby circuitry (see *Figure 24: Power supply overview*). SRAM2 content can be partially or fully preserved depending on RRSB1, RRSB2 and RRSB3 bits configuration in PWR_CR1. In this case, the low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The ULPMEN bit in the PWR_CR1 register must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode (only available when BOR level 0 is selected).

I/O states in Standby mode

In the Standby mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pulldown configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O. After wakeup from Standby mode, the pull-up/pull-down I/O configuration remains retained based on PWR_PUCRx/PWR_PDCRx as long as APC bit is set.

Some I/Os (listed in *Section 12: General-purpose I/Os (GPIO)*) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

I3C specific pull-ups are activated thanks to PWR I3C pull-up control registers 1 or 2. These registers must be configured before entering Standby mode in order to apply I3C pull-ups on corresponding I/Os. The I3C pull-up control bits must be cleared after exiting Standby mode, and after I3C initialization is done, to let I3C peripheral controls I/O pull-up activation.

The RTC outputs on PC13 and PB2 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. 22 wake-up pins multiplexed on eight events (WKUPx, x = 1 to 8) and the five tampers pins are available.

Entering Standby mode

The MCU enters the Standby mode as described in *Entering a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 87* for details on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

. The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 9.3: PWR functional description*).

- The real-time clock (RTC) and Tamper (TAMP) kernel clock is enabled by the RTCEN bit in the RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPRE bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.
- The I3Cx (x = 1, 2) reset pattern detection are enabled by the WUPEN9 and WUPEN10 bits in PWR_WUCR1.

Exiting Standby mode

The MCU exits the Standby mode as described in *Exiting a low-power mode*. The SBF status flag in the PWR status register (PWR_SR) indicates that the MCU was in Standby mode.

When exiting Standby mode, I/Os that were configured with pull-up or pull-down during Standby through PWR_PUCRx or PWR_PDCRx, keep this configuration upon exiting Standby mode until the APC bit in PWR_CR3 is cleared by the software. The application can release the retained I/O state (clear the retained pull-up/pull-down) by clearing the APC bit, after reconfiguring the GPIOs and related peripherals. Once APC is cleared, the I/Os state is configured according to the GPIOx registers. The content of the PWR_PUCRx or PWR_PDCRx registers is not lost and can be re-used for a sub-sequent entering into Standby mode.

Some I/Os (listed in Section 13 General-purpose I/Os (GPIO)) are used for JTAG/SW debug and have internal pull-up or pull-down activated after reset so is configured at this reset value, as well when exiting Standby mode.

For I/Os, with a pull-up or pull-down pre-defined after reset (some JTAG/SW I/Os) or with the GPIOx_PUPDR programming done after exiting from Standby, in case those programming is different from the PWR_PUCRx or PWR_PDCRx programmed value during Standby, both a pull-down and pull-up are applied until APC is cleared, releasing the PWR_PUCRx or PWR_PDCRx programmed value.

Figure 28. I/O states in Standby mode

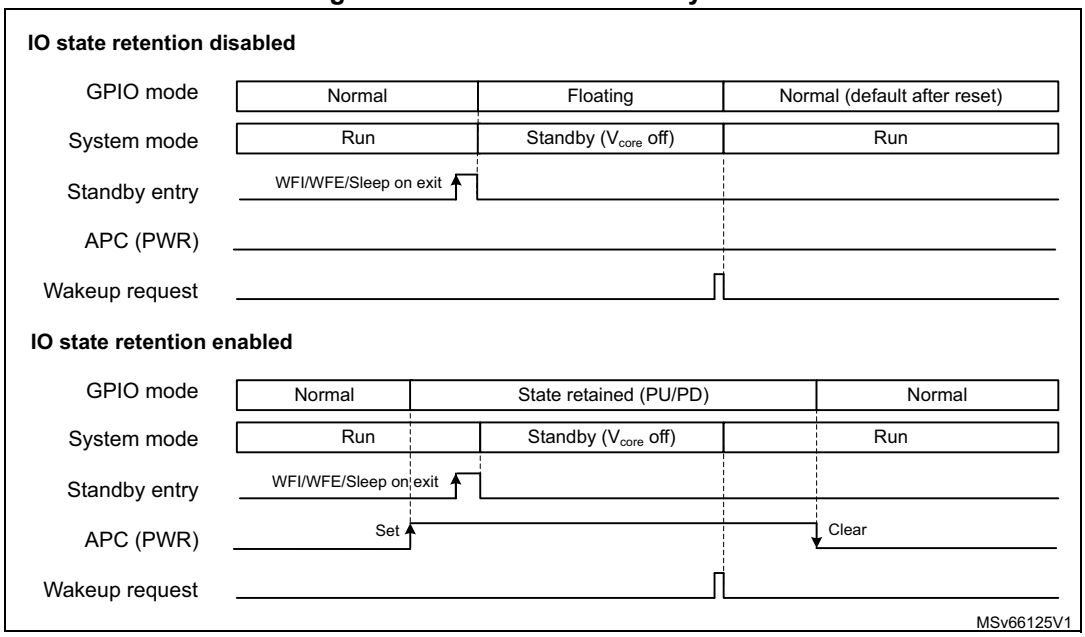

Table 87. Standby mode

Standby mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while:(1) – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 10X in PWR_CR1 – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 10X in PWR_CR1(1) – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wake-up source, cleared
Mode exit	– Any PWR wake-up line interrupt (WUF). The wake-up line source can be WKUP pins edge, RTC or TAMP event, IWDG early wake-up or I3C reset pattern detection – NRST pin external reset – BOR reset – IWDG reset
Wake-up latency	Reset phase. In case SRAM2 is retained in Standby, the wake-up latency is shorter as LDO setup is from low-power, instead of from OFF state. In the case where SRAM2 is in Standby, the wake-up latency is shorter because LDO setup is done in low-power, instead of in OFF state.

1. The Standby mode is also entered if LPMS = 11X in PWR_CR1 with BREN = 1 in PWR_BDCR.

Shutdown mode

The lowest power consumption is reached in Shutdown mode. It is based on the Deepsleep mode with the voltage regulator disabled. The core domain is consequently powered off. The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to backup domain is not supported.

I/O states in Shutdown mode

In the Shutdown mode, I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers (x = A, B, C, D, E, G, H)), or with a pull-down (see PWR_PDCRx registers (x = A, B, C, D, E, G, H)), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

I3C specific pull-ups are activated thanks to PWR I3C pull-up control registers 1 or 2. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

Some I/Os (listed in *Section 12: General-purpose I/Os (GPIO)*) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Shutdown mode setting to 1 their respective bit in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. 22 wake-up pins are multiplexed on eight events (WKUPx, x = 1 to 8) and the five RTC tampers pins are available.

Entering Shutdown mode

The MCU enters the Shutdown mode as described in *Entering a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 88* for details on how to enter Shutdown mode).

In Shutdown mode, the following features can be selected by programming individual control bits:

- The real-time clock (RTC) and Tamper (TAMP) kernel clock is enabled by the RTCEN bit in the RCC_BDCR.

Caution: In case of V_{DD} power-down, the RTC/TAMP and backup registers content is lost.

- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in the backup domain control register (RCC_BDCR).
- The I3Cx (x = 1, 2) reset pattern detection are enabled by the WUPEN9 and WUPEN10 bits in PWR_WUCR1.

Exiting Shutdown mode

The MCU exits the Shutdown mode as described in *Exiting a low-power mode*. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the

backup domain) are reset after a wake-up from Shutdown (see *Table 88* for more details on how to exit Shutdown mode).

When exiting Shutdown mode, I/Os that were configured with pull-up or pull-down during Shutdown through registers PWR_PUCRx or PWR_PDCRx lose their configuration and are configured in floating state or to their pull-up pull-down reset value (for some I/Os listed in *Section 12: General-purpose I/Os (GPIO)*).

Table 88. Shutdown mode

Shutdown mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 11X in PWR_CR1 with BREN = 0 in PWR_BDCR – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXT = 1 – No interrupt pending – LPMS = 11X in PWR_CR1 – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wake-up source, cleared
Mode exit	– Any PWR wake-up line interrupt (WUF). The wake-up line source can be WKUP pins edge, RTC or TAMP event or I3C reset pattern detection. – NRST pin external reset
Wake-up latency	Reset phase

Power mode output pins

In order to help the debug, two signals are available as device pin alternate functions:

- PWR_CSLEEP

When set, PWR_CSLEEP indicates that the CPU is in Sleep mode: WFI or WFE has been executed.

When cleared, PWR_CSLEEP indicates that the CPU is in Run mode.

- PWR_CSTOP

When set, PWR_CSTOP indicates that the device entered a Stop mode, and no autonomous peripheral requests its bus clock:

- WFI or WFE has been executed with CPU SLEEPDEEP = 1.
- No AHB/APB clock is running.

Note: The AHB/APB clocks run after WFI or WFE has been executed if an autonomous peripheral requests its bus clock in Stop mode. The peripherals bus clock request can delay or prevent the device to enter low-power modes (refer to Autonomous peripherals and Low-power modes).

The table below explains the MCU power mode depending on these signals states.

Table 89. Power modes output states versus MCU power modes

PWR_CSLEEP	PWR_CSTOP	MCU power mode(1)
0	0	Run mode
1	0	Sleep mode or Stop 0, Stop 1 or Stop 2 mode with AHB/APB clocks running
1	1	Stop 0, Stop 1 or Stop 2 mode with no AHB/APB clocks running

1. PWR_CSLEEP and PWR_CSTOP are not driven in Stop 3, Standby and Shutdown modes.

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop 1, Stop 2, Stop 3, Standby or Shutdown mode while the debug features are used. This is due to the fact that the Cortex-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Section 53.2.5: Debug and low-power modes*.

9.3.6 PWR security and privileged protection

PWR security protection

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, some PWR register fields can be secured against nonsecure access.

The PWR TrustZone security allows the following features to be secured through the PWR_SECCFGR register:

- Low-power mode
- Wake-up (WKUP) pins
- Voltage detection and monitoring
- VBAT mode
- I/Os pull-up/pull-down configuration

Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC: the voltage scaling configuration and the regulator booster (BOOSTEN) are secure.
- A GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode is secure.

Table 90 gives a summary of the PWR secured bits following the security configuration bit in PWR_SECCFGR. As soon as at least one function is configured to be secure, the PWR clock control is also secure in the RCC.

A nonsecure access to a secure-protected register bit is denied:

- The secured bits are not written (WI) with a nonsecure write access.
- The secured bits are read as 0 (RAZ) with a nonsecure read access.

A nonsecure write access to PWR_SECCFGR is WI and generates an illegal access event and an interrupt if enabled in the GTZC. It can be read with a nonsecure read access.

When the TrustZone security is disabled (TZEN = 0), PWR_SECCFGR is RAZ/WI and all other registers are nonsecure.

Table 90. PWR Security configuration summary

Secure configuration register	Security configuration bit	Register name	Secured bits	Nonsecure access on secure bits
PWR_SECCFGR	Not applicable(1)	PWR_SECCFGR	All bits	Read OK. WI and illegal access event
PWR_SECCFGR	At least one bit is set	PWR_PRIVCFGR	SPRIV	Read OK. WI
PWR_SECCFGR	LPMSEC	PWR_CR1	All bits	RAZ/WI
		PWR_CR2	All bits	
		PWR_SR	CSSF	WI
PWR_SECCFGR	VDMSEC	PWR_CR3	All bits	RAZ/WI
		PWR_SVMCR	All bits	RAZ/WI
PWR_SECCFGR	VBSEC	PWR_BDCR	All bits	RAZ/WI
		PWR_DBPR	All bits	RAZ/WI
PWR_SECCFGR	APCSEC	PWR_APCR	All bits	RAZ/WI
PWR_SECCFGR	WUPxSEC (x = 1 to 10)	PWR_WUCR1	WUPENx	RAZ/WI
		PWR_WUCR2	WUPPx	RAZ/WI
		PWR_WUCR3	WUSELx	RAZ/WI
		PWR_WUSCR	CWUFx	WI
RCC_SECCFGR	SYSCLKSEC	PWR_VOSR	R1EN, R2EN, BOOSTEN	RAZ/WI
GPIOx_SECCFGR (x=A,B..H)	SECy (y = 0..15)	PWR_PUCRx (x = A to H)	PUy (y = 0 to 15)	RAZ/WI
		PWR_PDCRx (x = A to H)	PDy (y = 0 to 15)	RAZ/WI
		PWR_I3CPUCR1	All bits	RAZ/WI
		PWR_I3CPUCR2	All bits	RAZ/WI

1. PWR_SECCFGR is always secure.

PWR privileged protection

By default, after a reset, all PWR registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR that can be written with privileged access only. PWR_PRIVCFGR can be read by secure and nonsecure, privileged and unprivileged accesses.

The SPRIV bit in PWR_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all PWR secure functions (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in *Table 90: PWR Security configuration summary*).

When the SPRIV bit is set in PWR_PRIVCFGR:

- The PWR secure bits can be written only with privileged access, including PWR_SECCFGR.
- The PWR secure bits can be read only with privileged access except PWR_SECCFGR and PWR_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit of PWR_PRIVCFGR can be written with privileged access only, secure or nonsecure. This bit configures the privileged access of all PWR securable functions that are configured as nonsecure (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in *Table 90: PWR Security configuration summary*).

When the NSPRIV bit is set in PWR_PRIVCFGR:

- The PWR securable bits that are configured as nonsecure, can be written only with privileged access.
- The PWR securable bits that are configured as nonsecure, can be read only with privileged access except PWR_PRIVCFGR that can be read by privileged or unprivileged accesses.
- The R1RDY, R2RDY and BOOSTRDY bits in PWR_VOSR, PWR_SR, PWR_SVMSR and PWR_WUSR, can be read with privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

9.4 PWR interrupts

The table below gives a summary of the interrupt sources and the way to control them.

Table 91. PWR interrupt requests

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep, Stop 0, 1, 2	Exit Stop 3, Standby, Shutdown
PWR(1)	Nonsecure wake-up interrupt	WUFx and (WUSELx ≠ 11) (x = 1 to 10)	WUPENx and (WUPxSEC = 0) (x = 1 to 10)	Write CWUFx = 1 (x = 1 to 10)	Yes	Yes
PWR_S(1)	Secure wake-up interrupt	WUFx and (WUSELx ≠ 11) (x = 1 to 10)	WUPENx and (WUPxSEC = 1) (x = 1 to 10)	Write CWUFx = 1 (x = 1 to 10)	Yes	Yes

Table 91. PWR interrupt requests (continued)

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep, Stop 0, 1, 2	Exit Stop 3, Standby, Shutdown
PVD_PVM	Programmable voltage detector through EXTI line16	PVDO	EXTI line 16 enabled	Write EXTI PIF16 = 1	Yes	No
	USB supply voltage monitor through EXTI line 19	VDDUSBRDY	EXTI line 19 enabled	Write EXTI PIF19 = 1	Yes	No
	VDDIO2 supply voltage monitor through EXTI line20	VDDIO2RDY	EXTI line 20 enabled	Write EXTI PIF20 = 1		
	Analog supply voltage monitor1 through EXTI line21	VDDA1RDY	EXTI line 21 enabled	Write EXTI PIF21 = 1		
	Analog supply voltage monitor2 through EXTI line22	VDDA2RDY	EXTI line 22 enabled	Write EXTI PIF22 = 1		

1. This interrupt is not generated for RTC, TAMP and IWDG internal wake-up lines.

9.5 PWR registers

The PWR registers can be accessed in word, half-word, and byte format, unless otherwise specified.

9.5.1 PWR control register 1 (PWR_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

Power-on reset value: 0x0000 0U00

This register is not affected by Standby mode.

This register is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	SRAM2PD	SRAM1PD	ULPMEN	RRSB3	RRSB2	RRSB1	Res.	LPMS[2:0]		
						rs	rs	rw	rw	rw	rw		rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **SRAM2PD**: SRAM2 power down

This bit is used to reduce the consumption by definitively powering off the SRAM2 until the next power-on reset.

0: SRAM2 powered on

1: SRAM2 powered off

Note: This bit is cleared upon power-on reset.

Bit 8 **SRAM1PD**: SRAM1 power down

This bit is used to reduce the consumption by definitively powering off the SRAM1 until the next power-on reset.

0: SRAM1 powered on

1: SRAM1 powered off

Note: This bit is cleared upon power-on reset.

Bit 7 **ULPMEN**: BOR0 ultra-low power mode

This bit is used to reduce the consumption by configuring the BOR in discontinuous mode. This bit has effect only when the BOR level 0 is selected, and when the device is in Standby mode. This bit must be set to reach the lowest power consumption in Standby mode.

0: BOR level 0 operating in continuous (normal) mode in Standby mode

1: BOR level 0 operating in discontinuous (ultra-low power) mode in Standby mode

Bit 6 **RRSB3**: SRAM2 page 3 retention in Standby mode

This bit is used to keep the SRAM2 page 3 content in Standby mode. The SRAM2 page 3 corresponds to the last 8 Kbytes of the SRAM2 (from SRAM2 base address + 0xE000 to SRAM2 base address + 0xFFFF).

0: SRAM2 page3 content not retained in Standby mode

1: SRAM2 page3 content retained in Standby mode

Note: This bit has no effect in Shutdown mode.

Bit 5 **RRSB2**: SRAM2 page 2 retention in Standby mode

This bit is used to keep the SRAM2 page 2 content in Standby mode. The SRAM2 page 2 corresponds to the 24 Kbytes of the SRAM2 (from SRAM2 base address + 0x8000 to SRAM2 base address + 0xDFFF).

0: SRAM2 page2 content not retained in Standby mode

1: SRAM2 page2 content retained in Standby mode

Note: This bit has no effect in Shutdown mode.

Bit 4 **RRSB1**: SRAM2 page 1 retention in Standby mode

This bit is used to keep the SRAM2 page 1 content in Standby mode. The SRAM2 page 1 corresponds to the first 32 Kbytes of the SRAM2 (from SRAM2 base address to SRAM2 base address + 0x7FFF).

0: SRAM2 page1 content not retained in Standby mode

1: SRAM2 page1 content retained in Standby mode

Note: This bit has no effect in Shutdown mode.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LPMS[2:0]**: Low-power mode selection

These bits select the low-power mode entered when the CPU enters Deepsleep mode.

000: Stop 0 mode

001: Stop 1 mode

010: Stop 2 mode

011: Stop 3 mode

100-101: Standby mode

110-111: Shutdown mode

9.5.2 PWR control register 2 (PWR_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

This register is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	FLASHFWU	SRAMFWU	PKARAMPDS	PRAMPDS	ICRAMPDS	Res.	Res.	Res.	Res.	Res.	Res.	SRAM2PDS3	SRAM2PDS2	SRAM2PDS1
		rw	rw	rw	rw	rw							rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM1PDS7	SRAM1PDS6	SRAM1PDS5	SRAM1PDS4	SRAM1PDS3	SRAM1PDS2	SRAM1PDS1
									rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **FLASHFWU**: Flash memory fast wake-up from Stop 0 and Stop 1 modes

This bit is used to obtain the best trade-off between low-power consumption and wake-up time when exiting Stop 0 or Stop 1 modes. When this bit is set, the flash memory remains in normal mode in Stop 0 and Stop 1 modes, which offers a faster startup time with higher consumption.

0: Flash memory enters low-power mode in Stop 0 and Stop 1 modes (lower-power consumption).

1: Flash memory remains in normal mode in Stop 0 and Stop 1 modes (faster wake-up time).

Bit 28 **SRAMFWU**: SRAM fast wake-up from Stop 0 and Stop 1 modes

This bit is used to obtain the best trade-off between low-power consumption and wake-up time. SRAMs wake-up time increases the wake-up time when exiting Stop 0 and 1 modes, and also increases the GPDMA1 access time to SRAMs during Stop modes.

0: SRAMs enter low-power mode in Stop 0 and Stop 1 modes (source biasing for lower-power consumption).

1: SRAMs remain in normal mode in Stop 0 and Stop 1 modes (higher consumption but no SRAM wake-up time).

Note: If one or several SRAMs are configured to be in power-down in Stop 1, Stop 2, and Stop 3 modes through the xRAMyPDS bits, setting this bit has no effect in Stop 1 mode.

Bit 27 **PKARAMPDS**: PKA SRAM power-down in Stop 1, Stop 2, and Stop 3 modes

0: PKA SRAM content retained in Stop modes

1: PKA SRAM content lost in Stop modes

Bit 26 **PRAMPDS**: FDCAN and USB SRAM power-down in Stop 1, Stop 2, and Stop 3 modes

0: FDCAN and USB SRAM content retained in Stop modes

1: FDCAN and USB SRAM content lost in Stop modes

Bit 25 **ICRAMPDS**: ICACHE SRAM power-down in Stop 1, Stop 2, and Stop 3 modes

0: ICACHE SRAM content retained in Stop modes

1: ICACHE SRAM content lost in Stop modes

Bits 24:19 Reserved, must be kept at reset value.

Bit 18 **SRAM2PDS3**: SRAM2 page 3 (8 Kbytes) power-down in Stop 1, Stop 2, and Stop 3 modes
0: SRAM2 page 3 content retained in Stop modes
1: SRAM2 page 3 content lost in Stop modes

Bit 17 **SRAM2PDS2**: SRAM2 page 2 (24 Kbytes) power-down in Stop 1, Stop 2, and Stop 3 modes
0: SRAM2 page 2 content retained in Stop modes
1: SRAM2 page 2 content lost in Stop modes

Bit 16 **SRAM2PDS1**: SRAM2 page 1 (32 Kbytes) power-down in Stop 1, Stop 2, and Stop 3 modes
0: SRAM2 page 1 content retained in Stop modes
1: SRAM2 page 1 content lost in Stop modes

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **SRAM1PDSi**: SRAM1 page i power-down in Stop 1, Stop 2, and Stop 3 modes (i = 7 to 1)
0: SRAM1 page i content retained in Stop modes
1: SRAM1 page i content lost in Stop modes
Note: Page 1 to 2 size is 16 Kbytes. Page 3 to 7 size is 32 Kbytes.

9.5.3 PWR control register 3 (PWR_CR3)

Address offset: 0x08

System reset value: 0b0000 0000 0000 0000 0000 0000 0000 0U00

Power-on reset value: 0x0000 0000

This register is not affected by Standby mode.

This register is protected against nonsecure access when VDMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FSTEN	REGSEL	Res.
													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSTEN**: Fast soft start
0: LDO/SMPS fast startup disabled (limited inrush current)
1: LDO/SMPS fast startup enabled

Bit 1 **REGSEL**: Regulator selection
0: LDO selected
1: SMPS selected
Note: REGSEL is reserved and must be kept at reset value in packages without SMPS.

Bit 0 Reserved, must be kept at reset value.

9.5.4 PWR voltage scaling register (PWR_VOSR)

Address offset: 0x0C

Reset value: 0x0002 0002

Some register bits are protected against nonsecure access depending on RCC_SECCFGR.

These bits can be protected against unprivileged access depending on PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOSTRDY	Res.	Res.	Res.	Res.	Res.	Res.	R2RDY	R1RDY
							r							r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOSTEN	Res.	Res.	Res.	Res.	Res.	Res.	R2EN	R1EN
							rw							rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **BOOSTRDY**: EPOD booster ready

This bit is set to 1 by hardware when the power booster startup time is reached. The system clock frequency can be switched higher than 24 MHz only after this bit is set. Disabling the booster clock when the booster is ready is forbidden.

0: Power booster not ready

1: Power booster ready

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **R2RDY**: Ready bit for V_{CORE} voltage range 2 selection

0: Range 2 not ready: voltage level < VOS range 2 level

1: Range 2 ready: voltage level ≥ VOS range 2 level

Note: R1RDY and R2RDY cannot be set at the same time.

Bit 16 **R1RDY**: Ready bit for V_{CORE} voltage range 1 selection

0: Range 1 not ready: voltage level < VOS range 1 level

1: Range 1 ready: voltage level ≥ VOS range 1 level

Note: R1RDY and R2RDY cannot be set at the same time

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **BOOSTEN**: EPOD booster enable

This bit is protected against nonsecure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

This bit must be set in range 1, and before increasing the system clock frequency above 24 MHz in range 2. The booster clock must be configured before setting this bit, and must not be disabled as long as the booster is enabled.

0: Booster disabled

1: Booster enabled

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **R2EN**: Voltage scaling range 2 selection

This bit is protected against nonsecure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

0: Voltage scaling range 2 disabled

1: Voltage scaling range 2 enabled

Note: R1EN and R2EN must be at opposite value. Any attempt to write R1EN and R2EN to the same value is ignored. Modifying R1EN and R2EN is possible only when current range is ready (R1RDY = R1EN and R2RDY = R2EN).

Bit 0 **R1EN**: Voltage scaling range 1 selection

This bit is protected against nonsecure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

0: Voltage scaling range 1 disabled

1: Voltage scaling range 1 enabled

Note: R1EN and R2EN must be at opposite value. Any attempt to write R1EN and R2EN to the same value is ignored. Modifying R1EN and R2EN is possible only when current range is ready (R1RDY = R1EN and R2RDY = R2EN).

9.5.5 PWR supply voltage monitoring control register (PWR_SVMCR)

Address offset: 0x10

Reset value: 0x0000 0000

This register is protected against nonsecure access when VDMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	ASV	IO2SV	USV	AVM2EN	AVM1EN	IO2VMEN	UVMEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDLS[2:0]			PVDE	Res.	Res.	Res.	Res.
								rw	rw	rw	rw				

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ASV**: V_{DDA} independent analog supply valid

This bit is used to validate the V_{DDA} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the analog peripherals. If V_{DDA} is not always present in the application, the V_{DDA} voltage monitor can be used to determine whether this supply is ready or not.

0: V_{DDA} not present: logical and electrical isolation is applied to ignore this supply.

1: V_{DDA} valid

Bit 29 **IO2SV**: V_{DDIO2} independent I/O supply valid

This bit is used to validate the V_{DDIO2} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PG[15:2]. If V_{DDIO2} is not always present in the application, the V_{DDIO2} voltage monitor can be used to determine whether this supply is ready or not.

0: V_{DDIO2} not present: logical and electrical isolation is applied to ignore this supply.

1: V_{DDIO2} valid

Bit 28 **USV**: V_{DDUSB} independent USB supply valid
This bit is used to validate the V_{DDUSB} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USB peripheral. If V_{DDUSB} is not always present in the application, the V_{DDUSB} voltage monitor can be used to determine whether this supply is ready or not.
0: V_{DDUSB} not present: logical and electrical isolation is applied to ignore this supply.
1: V_{DDUSB} valid

Bit 27 **AVM2EN**: V_{DDA} independent analog supply voltage monitor 2 enable (1.8 V threshold)
0: V_{DDA} voltage monitor 2 disabled
1: V_{DDA} voltage monitor 2 enabled

Bit 26 **AVM1EN**: V_{DDA} independent analog supply voltage monitor 1 enable (1.6 V threshold)
0: V_{DDA} voltage monitor 1 disabled
1: V_{DDA} voltage monitor 1 enabled

Bit 25 **IO2VMEN**: V_{DDIO2} independent I/O voltage monitor enable
0: V_{DDIO2} voltage monitor disabled
1: V_{DDIO2} voltage monitor enabled

Bit 24 **UVMEN**: V_{DDUSB}independent USB voltage monitor enable
0: V_{DDUSB} voltage monitor disabled
1: V_{DDUSB} voltage monitor enabled

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:5 **PVDLS[2:0]**: Programmable voltage detector (PVD) level selection
These bits select the voltage threshold detected by the PVD.
000: V_{PVD0} around 2.0 V
001: V_{PVD1} around 2.2 V
010: V_{PVD2} around 2.4 V
011: V_{PVD3} around 2.5 V
100: V_{PVD4} around 2.6 V
101: V_{PVD5} around 2.8 V
110: V_{PVD6} around 2.9 V
111: External input analog voltage PVD_IN (compared internally to VREFINT)

Bit 4 **PVDE**: Programmable voltage detector enable
0: PVD disabled
1: PVD enabled

Bits 3:0 Reserved, must be kept at reset value.

9.5.6 PWR wake-up control register 1 (PWR_WUCR1)

Address offset: 0x14

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit WUPENi is protected against nonsecure access when WUPiSEC = 1 in PWR_SECCFGR.

Each bit WUPENi is protected against unprivileged access when WUPiSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPiSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **WUPENi**: Wake-up line WKUPi enable (i = 10 to 1)
0: Wake-up line WKUPi disabled
1: Wake-up line WKUPi enabled

9.5.7 PWR wake-up control register 2 (PWR_WUCR2)

Address offset: 0x18

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit WUPPi is protected against nonsecure access when WUPiSEC = 1 in PWR_SECCFGR. Each bit WUPPi is protected against unprivileged access when WUPiSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPiSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WUPPi**: Wake-up line WKUP8 polarity (i = 8 to 1)
This bit must be configured when WUPENi = 0. It has no effect when WUSELi[1:0] = 11.
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

9.5.8 PWR wake-up control register 3 (PWR_WUCR3)

Address offset: 0x1C

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bitfield WUSELi[1:0] is protected against nonsecure access when WUPiSEC = 1 in PWR_SECCFGR. Each bitfield WUSELi[1:0] is protected against unprivileged access when WUPiSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPiSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WUSELi[1:0]**: Wake-up line WKUPi selection (i = 8 to 1)
This bitfield must be configured when WUPENi = 0.
00: WKUPi_0
01: WKUPi_1
10: WKUPi_2
11: WKUPi_3

9.5.9 PWR backup domain control register (PWR_BDCR)

Address offset: 0x24

System reset value: 0xUUUU UUUU

Backup domain reset value: 0x0000 0000

This register is not affected by Standby mode.

This register is protected against nonsecure access when VBSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VBSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBRS	VBE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **VBRS**: V_{BAT} charging resistor selection
0: V_{BAT} charged through a 5 kΩ resistor
1: V_{BAT} charged through a 1.5 kΩ resistor

Bit 0 **VBE**: V_{BAT} charging enable
0: V_{BAT} battery charging disabled
1: V_{BAT} battery charging enabled

9.5.10 PWR disable backup domain register (PWR_DBPR)

Address offset: 0x28

Reset value: 0x0000 0000

This register is protected against nonsecure access when VBSEC = 1 in PWR_SECCFGR.
This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VBSEC = 0 and NSPRIV = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBP
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DBP**: Disable backup domain write protection

In reset state, all registers and SRAM in backup domain are protected against parasitic write access. This bit must be set to enable the write access to these registers.

0: Write access to backup domain disabled

1: Write access to backup domain enabled

9.5.11 PWR security configuration register (PWR_SECCFGR)

Address offset: 0x30

Reset value: 0x0000 0000

This register can be written only when the access is secure. It can be read by secure or nonsecure access. This register is write-protected against unprivileged write access when SPRIV = 1 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **APCSEC**: Pull-up/pull-down secure protection

0: PWR_APCR can be read and written with secure or nonsecure access.

1: PWR_APCR can be read and written only with secure access.

Bit 14 **VBSEC**: Backup domain secure protection

0: PWR_BDCR and PWR_DBPR can be read and written with secure or nonsecure access.

1: PWR_BDCR and PWR_DBPR can be read and written only with secure access.

Bit 13 **VDMSEC**: Voltage detection and monitoring secure protection

0: PWR_SVMCR and PWR_CR3 can be read and written with secure or nonsecure access.

1: PWR_SVMCR and PWR_CR3 can be read and written only with secure access.

Bit 12 **LPMSEC**: Low-power mode secure protection

0: PWR_CR1, PWR_CR2, and CSSF bit in the PWR_SR can be read and written with secure or nonsecure access.

1: PWR_CR1, PWR_CR2, and CSSF bit in the PWR_SR can be read and written only with secure access.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **WUPiSEC**: WUPi secure protection (i = 10 to 1)

0: Bits related to the WKUPi line in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3, and PWR_WUSCR can be read and written with secure or nonsecure access.

1: Bits related to the WKUPi line in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3, and PWR_WUSCR can be read and written only with secure access.

9.5.12 PWR privilege control register (PWR_PRIVCFGR)

Address offset: 0x34

Reset value: 0x0000 0000

This register can be written only when the access is privileged. It can be read by privileged or unprivileged access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NS PRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: PWR nonsecure function privilege configuration

This bit is set and reset by software. It can be written only by privileged access, secure or nonsecure.

0: Read and write to PWR nonsecure functions can be done by privileged or unprivileged access.

1: Read and write to PWR nonsecure functions can be done by privileged access only.

Bit 0 **SPRIV**: PWR secure function privilege configuration

This bit is set and reset by software. It can be written only by a secure privileged access.

0: Read and write to PWR secure functions can be done by privileged or unprivileged access.

1: Read and write to PWR secure functions can be done by privileged access only.

9.5.13 PWR status register (PWR_SR)

Address offset: 0x38

Reset value: 0x0000 0000

Some bits are protected against nonsecure access depending on PWR_SECCFGR. Some bits are protected against unprivileged access depending on PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	CSSF
													r	r	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **SBF**: Standby flag

This bit is set by hardware when the device enters the Standby mode, and is cleared by writing 1 to the CSSF bit, or by a power-on reset. It is not cleared by the system reset.

0: The device did not enter Standby mode.

1: The device entered Standby mode.

Bit 1 **STOPF**: Stop flag

This bit is set by hardware when the device enters a Stop mode, and is cleared by software by writing 1 to the CSSF bit.

0: The device did not enter any Stop mode.

1: The device entered a Stop mode.

Bit 0 **CSSF**: Clear Stop and Standby flags

This bit is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR.
This bit is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.
Writing 1 to this bit clears the STOPF and SBF flags.

9.5.14 PWR supply voltage monitoring status register (PWR_SVMSR)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	VDDA2RDY	VDDA1RDY	VDDIO2RDY	VDDUSBRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	Res.	REGS	Res.
											r			r	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **VDDA2RDY**: V_{DDA} ready versus 1.8 V voltage monitor

0: V_{DDA} is below the threshold of the V_{DDA} voltage monitor 2 (around 1.8 V).

1: V_{DDA} is equal or above the threshold of the V_{DDA} voltage monitor 2 (around 1.8 V).

Bit 26 **VDDA1RDY**: V_{DDA} ready versus 1.6 V voltage monitor

0: V_{DDA} is below the threshold of the V_{DDA} voltage monitor 1 (around 1.6 V).

1: V_{DDA} is equal or above the threshold of the V_{DDA} voltage monitor 1 (around 1.6 V).

Bit 25 **VDDIO2RDY**: V_{DDIO2} ready

0: V_{DDIO2} is below the threshold of the V_{DDIO2} voltage monitor.

1: V_{DDIO2} is equal or above the threshold of the V_{DDIO2} voltage monitor.

Bit 24 **VDDUSBRDY**: V_{DDUSB} ready

0: V_{DDUSB} is below the threshold of the V_{DDUSB} voltage monitor.

1: V_{DDUSB} is equal or above the threshold of the V_{DDUSB} voltage monitor.

Bits 23:5 Reserved, must be kept at reset value.

Bit 4 **PVDO**: Programmable voltage detector output

0: V_{DD} is equal or above the PVD threshold selected by PVDLS[2:0].

1: V_{DD} is below the PVD threshold selected by PVDLS[2:0].

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **REGS**: Regulator selection

0: LDO selected

1: SMPS selected

Bit 0 Reserved, must be kept at reset value.

9.5.15 PWR wake-up status register (PWR_WUSR)

Address offset: 0x44

Reset value: 0x0000 0000

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **WUFi**: Wake-up flag i (i = 10 to 1)

This bit is set when a wake-up event is detected on WKUPi line. This bit is cleared by writing 1 in the CWUFi bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPENi = 0. If WUSEL = 11, this bit is cleared by hardware when all internal wake-up source are cleared.

9.5.16 PWR wake-up status clear register (PWR_WUSCR)

Address offset: 0x48

Reset value: 0x0000 0000

Each bit CWUFi is protected against nonsecure access when WUPiSEC = 1 in PWR_SECCFGR. Each bit CWUFi is protected against unprivileged access when WUPiSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPiSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						w	w	w	w	w	w	w	w	w	w

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **CWUFi**: Wake-up flag i clear (i = 10 to 1)

Writing 1 to this bit clears the WUFi flag in PWR_WUSR.

9.5.17 PWR apply pull configuration register (PWR_APCR)

Address offset: 0x4C

Reset value: 0x0000 0000

This register is not affected by Standby mode.

This register is protected against nonsecure access when APCSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when APCSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when APCSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APC
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **APC**: Apply pull-up and pull-down configuration

When this bit is set, the I/O pull-up and pull-down configurations defined in PWR_PUCRx and PWR_PDCRx are applied.

When this bit is cleared, PWR_PUCRx and PWR_PDCRx are not applied to the I/Os.

Note: When APC is set, I/Os configurations from GPIO registers are still applied in Run and Sleep modes (ORed with PWR registers). Care must be taken to define a coherent I/O configuration in GPIO and PWR pull-up/pull-down control registers.

9.5.18 PWR port A pull-up control register (PWR_PUCRA)

Address offset: 0x50

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit PUy is protected against nonsecure access when SECy = 1 in GPIOA_SECCFGR. Each bit PUy is protected against unprivileged access when SECy = 1 in GPIOA_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **PU15**: Port A pull-up bit 15

When set, each bit activates the pull-up on PA15 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD15 bit is also set.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bit 14 Reserved, must be kept at reset value.

Bits 13:0 **PUy**: Port A pull-up bit y (y = 13 to 0)

When set, each bit activates the pull-up on PAy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.5.19 PWR port A pull-down control register (PWR_PDCRA)

Address offset: 0x54

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit PDy is protected against nonsecure access when SECy = 1 in GPIOA_SECCFGR.
Each bit PDy is protected against unprivileged access when SECy = 1 in GPIOA_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **PD14**: Port A pull-down bit 14

When set, each bit activates the pull-down on PA14 when the APC bit is set in PWR_APCR.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bit 13 Reserved, must be kept at reset value.

Bits 12:0 **PDy**: Port A pull-down bit y (y = 12 to 0)

When set, each bit activates the pull-down on PAy when the APC bit is set in PWR_APCR.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.5.20 PWR port B pull-down control register (PWR_PDCRB)

Address offset: 0x5C

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit PDy is protected against nonsecure access when SECy = 1 in GPIOB_SECCFGR.
Each bit PDy is protected against unprivileged access when SECy = 1
in GPIOB_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:5 **PDy**: Port B pull-down bit y (y = 15 to 5)

When set, each bit activates the pull-down on PBy when the APC bit is set in PWR_APCR.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bit 4 Reserved, must be kept at reset value.

Bits 3:0 **PDy**: Port B pull-down bit y (y = 3 to 0)

When set, each bit activates the pull-down on PBy when the APC bit is set in PWR_APCR.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.5.21 PWR port x pull-up control register (PWR_PUCRx) (x = B to E)

Address offset: Port B: 0x58

Address offset: Port C: 0x60

Address offset: Port D: 0x68

Address offset: Port E: 0x70

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit PUy is protected against nonsecure access when SECy = 1 in GPIOx_SECCFGR.

Each bit PUy is protected against unprivileged access when SECy = 1 in GPIOx_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SEC y = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PUy**: Port x pull-up bit y (y = 15 to 0)

When set, each bit activates the pull-up on Pxy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.5.22 PWR port x pull-down control register (PWR_PDCRx) (x = C to E)

Address offset: Port C: 0x64

Address offset: Port D: 0x6C

Address offset: Port E: 0x74

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit PDy is protected against nonsecure access when SECy = 1 in GPIOx_SECCFGR.

Each bit PDy is protected against unprivileged access when SECy = 1 in GPIOx_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PU3**: Port H pull-up bit 3

When set, each bit activates the pull-up on PH3 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD3 bit is also set.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **PUy**: Port H pull-up bit y (y = 1 to 0)

When set, each bit activates the pull-up on PHy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.5.26 PWR port H pull-down control register (PWR_PDCRH)

Address offset: 0x8C

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit PDy is protected against nonsecure access when SECy = 1 in GPIOH_SECCFGR.
Each bit PDy is protected against unprivileged access when SECy = 1

in GPIOH_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PD3**: Port H pull-down bit 3

When set, each bit activates the pull-down on PH3 when the APC bit is set in PWR_APCR.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **PDy**: Port H pull-down bit y (y = 1 to 0)

When set, each bit activates the pull-down on PHy when the APC bit is set in PWR_APCR.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.5.27 PWR I3C pull-up control register 1 (PWR_I3CPUCR1)

Address offset: 0xB0

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit Pxy_I3CPU is protected against nonsecure access when SECy = 1 in GPIOx_SECCFGR.

Each bit Pxy_I3CPU is protected against unprivileged access when SECy = 1 in GPIOx_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:9 **PBx_I3CPU**: Port B pin x I3C pull-up (x = 14 to 12)

When set, the bit activates the I3C pull-up on PBx.

Bits 8:6 **PBy_I3CPU**: Port B pin y I3C pull-up (y = 10 to 8)
When set, the bit activates the I3C pull-up on PBy.

Bit 5 **PB6_I3CPU**: Port B pin 6 I3C pull-up
When set, the bit activates the I3C pull-up on PB6.

Bit 4 **PB2_I3CPU**: Port B pin 2 I3C pull-up
When set, the bit activates the I3C pull-up on PB2.

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **PAy_I3CPU**: Port A pin y I3C pull-up (y = 7 to 6)
When set, the bit activates the I3C pull-up on PAy.

Bit 0 **PA1_I3CPU**: Port A pin 1 I3C pull-up
When set, the bit activates the I3C pull-up on PA1.

9.5.28 PWR I3C pull-up control register 2 (PWR_I3CPUCR2)

Address offset: 0xB4

Reset value: 0x0000 0000

This register is not affected by Standby mode.

Each bit Pxy_I3CPU is protected against nonsecure access when SECy = 1 in GPIOx_SECCFGR.

Each bit Pxy_I3CPU is protected against unprivileged access when SECy = 1 in GPIOx_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw		rw	rw	rw	rw		rw	rw		rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **PH3_I3CPU**: Port H pin 3 I3C pull-up
When set, the bit activates the I3C pull-up on PH3.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **PGx_I3CPU**: Port G pin x I3C pull-up (x = 14 to 13)
When set, the bit activates the I3C pull-up on PGx.

Bits 7:6 **PGy_I3CPU**: Port G pin y I3C pull-up (y = 8 to 7)
When set, the bit activates the I3C pull-up on PGy.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **PDy_I3CPU**: Port D pin y I3C pull-up (y = 13 to 12)
When set, the bit activates the I3C pull-up on PDy.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **PCy_I3CPU**: Port C pin 1 I3C pull-up (y = 1 to 0)
When set, the bit activates the I3C pull-up on PCy.

10 Reset and clock control (RCC)

10.1 RCC introduction

The reset and clock control (RCC) manages the different kinds of reset, and generates all clocks for the bus and peripherals.

10.2 RCC functional description

10.2.1 RCC pins and internal signals

The table below lists the RCC inputs and output signals connected to package pins or balls.

Table 93. RCC input/output signals connected to package pins or balls

Pin name	Pin type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO	O	Output clock for external devices
MCO2	O	Output clock 2 for external devices
LSCO	O	Low-speed output clock for external devices
AUDIOCLK	I	External kernel clock input for SAI1 and ADF1

10.2.2 RCC reset functional description

There are three types of reset:

- a system reset
- a power reset
- a backup domain reset

Power reset

A power reset is generated when one of the following events occurs:

- a brownout reset (BOR)
- when exiting Standby mode
- when exiting Shutdown mode

A BOR sets all registers to their reset values except the ones in the backup domain.

When exiting Standby mode, all registers in the core domain are set to their reset value. Registers outside the core domain (RTC, TAMP, WKUP, IWDG, and Standby/Shutdown mode control) are not impacted.

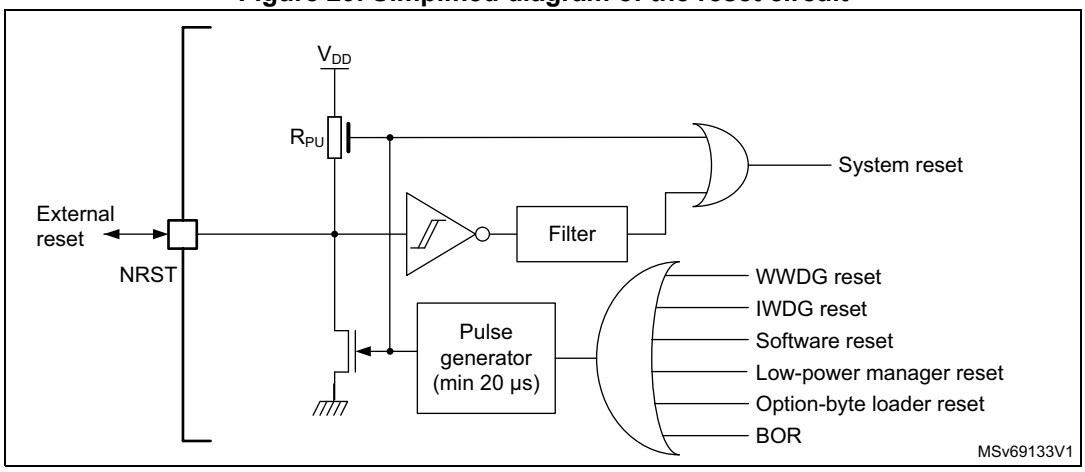
When exiting Shutdown mode, a brownout reset is generated, resetting all registers except those in the backup domain.

System reset

A system reset sets all registers to their reset values except the reset flags in RCC_CSR, and the registers in the backup domain.

A system reset is generated when one of the following events occurs:

- a low level on the NRST pin (external reset)
- a window watchdog event (WWDG reset)
- an independent watchdog event (IWDG reset)
- a software reset (SW reset)
- a low-power mode security reset
- an option-byte loader reset
- a brownout reset



The reset source can be identified by checking the reset flags in RCC_CSR.

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected via the boot option bytes.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case of an internal reset, the internal pull-up R_{PU} is deactivated in order to save the power consumption through the pull-up resistor.

Figure 29. Simplified diagram of the reset circuit

- Software reset

  The SYSRESETREQ bit in Cortex-M33 application interrupt and reset control register must be set to force a software reset on the device.

- Low-power mode security reset

  To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

  – Entering Standby mode: this type of reset is enabled by resetting NRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.

  – Entering Stop mode: this type of reset is enabled by resetting NRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

  – Entering Shutdown mode: this type of reset is enabled by resetting NRST_SHDW bit in user option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

  For further information on the user option bytes, refer to *Section 7.4.2: Option-byte programming*.

- Option byte loader reset

  The option byte loader reset is generated when the OBL_LAUNCH bit is set in FLASH_CR. This bit is used to launch the option byte loading by software.

Backup domain reset

The backup domain has two specific resets.

A backup domain reset is generated when one of the following events occurs:

- a software reset, triggered by setting the BDRST bit in RCC_BDCR
- a V_{DD} or V_{BAT} power on, if both supplies have previously been powered off

A backup domain reset affects the LSE oscillator, the RTC, the TAMP, the backup registers, and RCC_BDCR.

10.2.3 RCC clock functional description

Three different clock sources can be used to drive the system clock (SYSCLK):

- HSI16: high-speed internal 16 MHz RC oscillator clock
- MSIS: multi-speed internal RC oscillator clock, from 3 to 96 MHz
- HSE: high-speed external crystal or clock, from 4 to 50 MHz

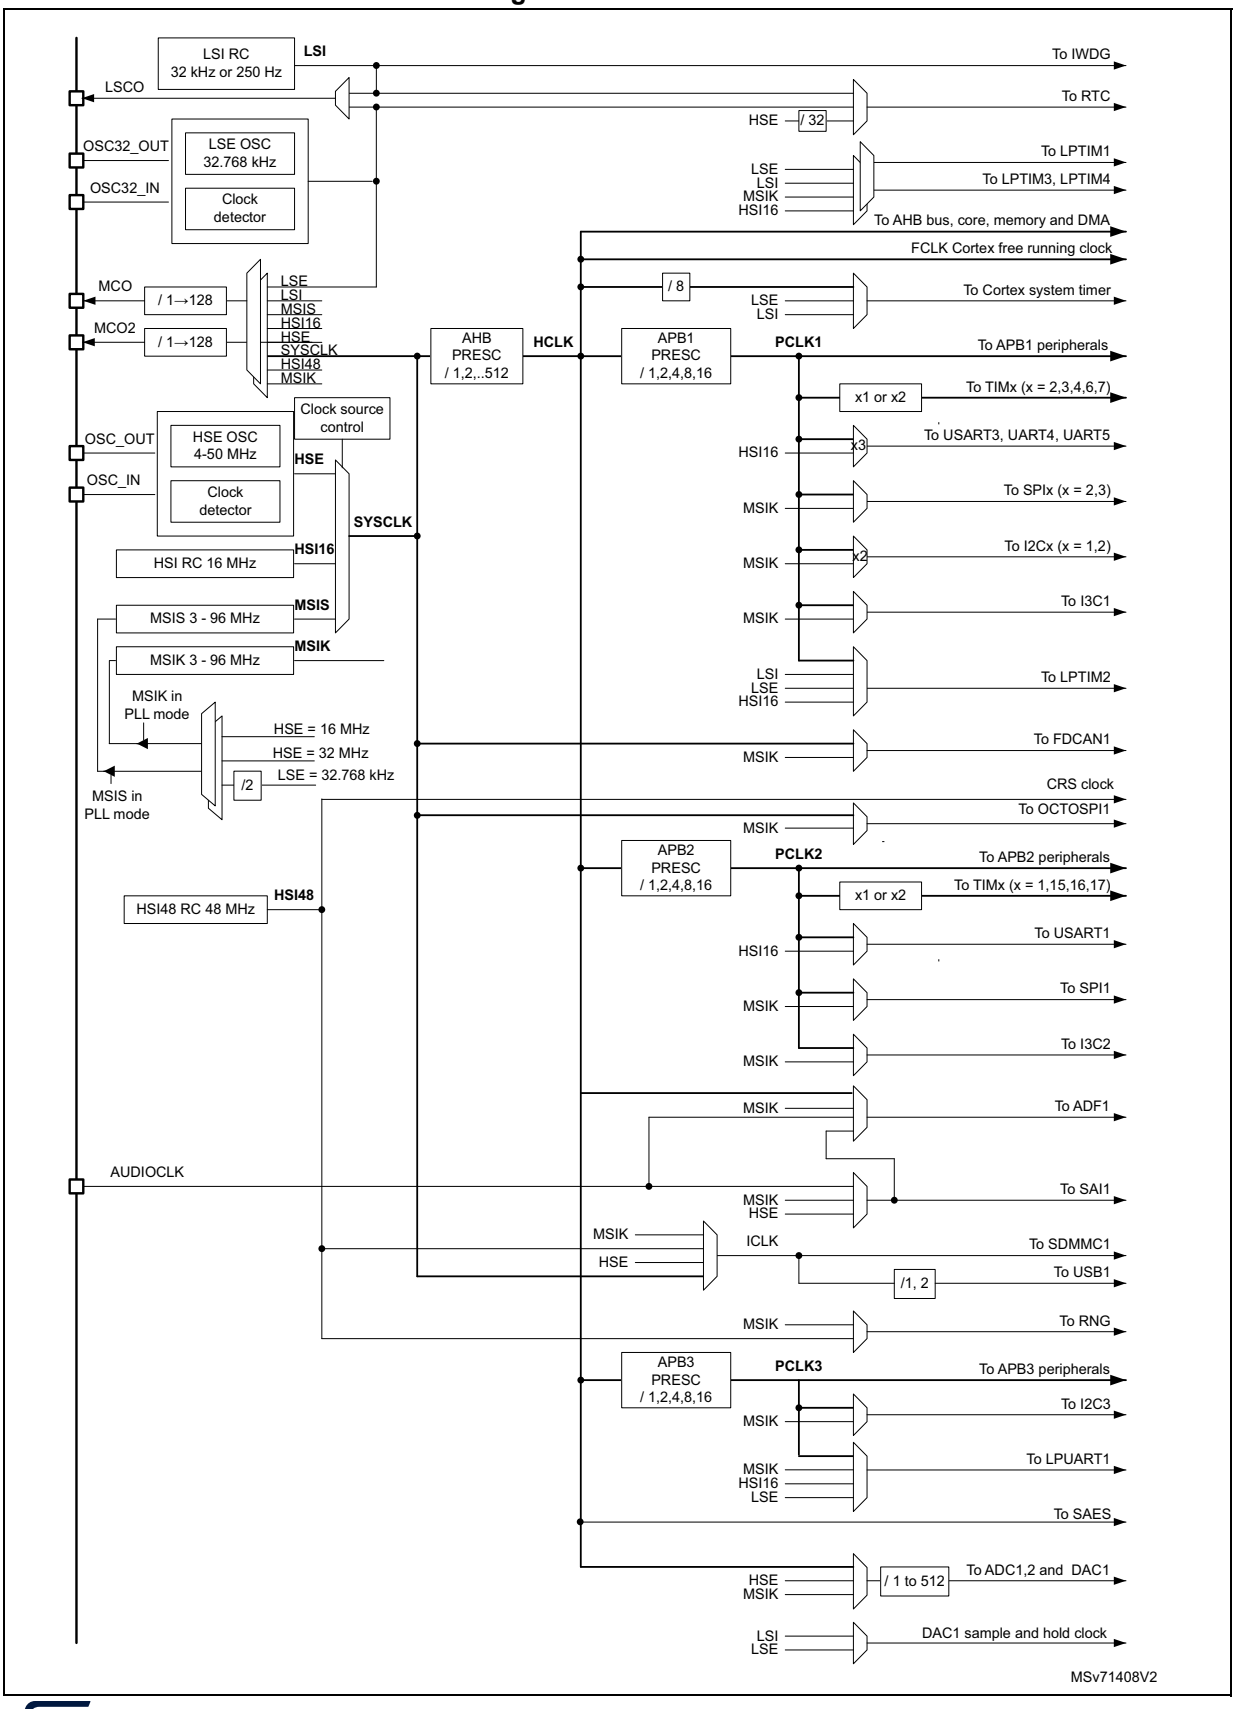
The MSIS is used as system clock source after startup from reset, configured at 12 MHz.

The devices have the following additional clock sources:

- MSIK: multi-speed internal RC oscillator clock used for peripherals kernel clocks, from 3 to 96 MHz
- LSI: 32 kHz/250 Hz low-speed internal RC that drives the independent watchdog and optionally the RTC used for automatic wake-up from Stop and Standby modes
- LSE: 32.768 kHz low-speed external crystal or clock that optionally drives the real-time clock (rtc_ck)
- HSI48: internal 48 MHz RC that potentially drives the USB, the SDMMC and the RNG

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1, APB2, and APB3 domains. The maximum frequency of the AHB and APB domains is 96 MHz.



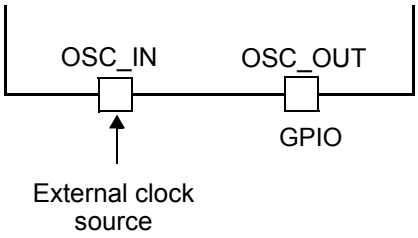
All peripheral clocks are derived from their bus clock (HCLK, PCLK1, PCLK2, or PCLK3), except the following ones that receive an independent kernel clock: USB, SDMMC1, RNG, ADCx (x = 1, 2), DAC1, U(S)ARTx (x = 1, 3 to 5), LPUART1, I2Cx (x = 1 to 3), I3Cx (x = 1, 2), SPIx (x = 1 to 3), OCTOSPI1, SAI1, ADF1, FDCAN1, LPTIMx (x = 1 to 4). Most of these kernel clocks can be selected by software from various sources, thanks to RCC_CCIPRx registers (x = 1 to 3).

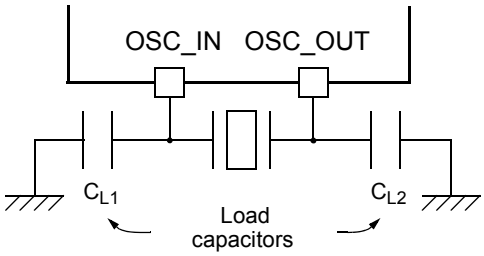
In addition, the RTC kernel clock is selected by software in RCC_BDCR. The IWDG clock is always the LSI 32 kHz clock.

The RCC feeds the core system timer (SysTick) external clock with the AHB clock (HCLK) divided by eight, or LSE, or LSI. The SysTick can work either with this clock or directly with the core clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex-M33 free-running clock.

Figure 30. Clock tree





HSE clock

The high-speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

Table 94. HSE/LSE clock sources

Clock source	Hardware configuration
External clock	
Crystal/ceramic resonators	

- External crystal/ceramic resonator (HSE crystal)

  The external oscillator has the advantage of producing a very accurate rate on the main clock.

  The associated hardware configuration is shown in *Table 94: HSE/LSE clock sources*. Refer to the electrical characteristics section of the datasheet for more details.

  The HSERDY flag in RCC_CR indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

  The HSE crystal can be switched on and off using the HSEON bit in RCC_CR.

- External source (HSE bypass)

  In this mode, an external clock source must be provided. This mode is selected by setting the HSEBYP and HSEON bits in RCC_CR. The external clock signal with

~40 - 60 % duty cycle depending on the frequency (refer to the datasheet) must drive the OSC_IN pin while the OSC_OUT pin can be used a GPIO (see *Table 94: HSE/LSE clock sources*). The bypass mode is optimized for square input signals when HSEEXT = 1. If the input is a sine wave or triangle signal, HSEEXT must be kept at 0 (analog bypass mode).

HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator. However, even with calibration, the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wake-up from Stop modes (Stop 0, Stop 1, Stop 2, or Stop 3). Refer to RCC_CFGR1. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to *Clock security system (CSS)*.

- HSI16 calibration

  The RC oscillator frequencies may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at T_A = 25°C.

  After reset, the factory calibration value is loaded in the HSICAL[11:0] bits in RCC_ICSCR3.

  If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. The HSI16 frequency can be trimmed in the application using the HSITRIM[4:0] in RCC_ICSCR3.

  For more details on how to measure the HSI16 frequency variation, refer to *Internal/external clock measurement with TIM15/TIM16/TIM17*.

  The HSIRDY flag in RCC_CR indicates if the HSI16 RC is stable or not. At startup, the HSI16 RC output clock is not released until this bit is set by hardware.

  The HSI16 RC can be switched on and off using the HSION bit in RCC_CR.

  The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to *Clock security system (CSS)*.

MSI (MSIS and MSIK) clocks

The MSI is made of two internal RC oscillators: MSIRC0 at 96 MHz and MSIRC1 at 24 MHz. Each oscillator feeds a prescaler providing a division by 1, 2, 4, or 8. Two output clocks are generated from these divided oscillators: MSIS, that can be selected as system clock, and MSIK, that can be selected by some peripherals as kernel clock.

Figure 31. MSI block diagram

For each output clock MSIS and MSIK, the oscillator source is selected using respectively MSISSEL and MSIKSEL, and division factor is selected using respectively MSISDIV[1:0] and MSIKDIV[1:0] in RCC_ICSCR1. A total of six different frequencies are available, generated from the two internal RCs, as shown in *Table 95*. 24 MHz and 12 MHz can be generated from both RCs.

In case no higher frequency is needed in the application, it is recommended to select MSIRC1 to get lower consumption.

In case 48 MHz or 96 MHz frequency is also needed in addition to 24 or 12 MHz, it is recommended to select MSIRC0, and generate both frequencies from the same oscillator rather than using both RCs, in order to save additional RC consumption.

Table 95. MSIS and MSIK ranges per internal MSIRCs (PLL mode disabled)

MSIRC0	MSIRC1
Range 0: 96 MHz	Range 4: 24 MHz
Range 1: 48 MHz	Range 5: 12 MHz
Range 2: 24 MHz	Range 6: 6 MHz
Range 3: 12 MHz	Range 7: 3 MHz

Note: Refer to datasheet for complete MSI frequency characteristics in MSI-mode and in PLL mode.

The MSIS clock is used as system clock after restart from reset, wake-up from Standby and Shutdown low-power modes. After restart from reset or when exiting Shutdown mode, the MSIS and MSIK frequencies are set to their default value 12 MHz, generated from MSIRC1. The selected oscillator is always MSIRC1 when exiting Standby mode, and the frequency range can be adjusted by software between 3, 6 or 12 MHz, using respectively the MSISDIVS[1:0] and MSIKDIVS[1:0] fields. Refer to RCC_CSR.

The MSIS clock can be selected as system clock after a wake-up from Stop mode (Stop 0, Stop 1, Stop 2, or Stop 3) depending on STOPWUCK in RCC_CFGR1. It can also be used

as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to *Clock security system (CSS)*.

The MSI oscillator has the advantage of providing a low-cost (no external components) low-power clock source. In addition, when used in PLL mode with the LSE or HSE, the MSI provides a very accurate clock source that can be used by the USB peripheral.

MSISRDY and MSIKRDY flags in RCC_CR indicate whether the MSIS and MSIK RC are stable or not. At startup, the MSIS and MSIK RC output clocks are not released until their respective bit is set by hardware. The MSIS and MSIK RC can be switched on and off by using the MSISON and MSIKON bits in RCC_CR.

- Hardware auto-calibration with LSE or HSE (PLL mode)

  When a 32.768 kHz, a 32 MHz or a 16 MHz external oscillator is present in the application, it is possible to configure MSIS, MSIK or both in a PLL mode. The long term accuracy of the MSI in PLL mode is the one of the external oscillator.

  Using the MSI in PLL mode with LSE provides a low-power solution to get an accurate high-speed clock.

  The MSIS is in PLL mode when the internal MSIRCx (x = 0,1) selected for MSIS is configured in PLL mode. The MSIK is in PLL mode when the internal MSIRCx (x = 0,1) selected for MSIK is configured in PLL mode.

  Either MSIS or MSIK, with MSIRC1 selected, must be enabled and ready before enabling MSIRC1 PLL mode, and in the same way either MSIS or MSIK, with MSIRC0 selected, must be enabled and ready before enabling MSIRC0 PLL mode.

  When LSE or HSE is used for PLL mode, this oscillator must be enabled and ready before selecting it as input for MSIRCx PLL mode.

  MSIRCx PLL mode is configured to operate with LSE when the corresponding MSIPLLxSEL = 0, or with HSE at 32 MHz or 16 MHz when the corresponding MSIPLLxSEL = 1 in RCC_ICSCR1. In case HSE is at 32 MHz, it must be divided by 2 by setting MSIHSINDIV bit.

  Once input clock is selected, the MSIRCx PLL mode is enabled by setting the corresponding MSIPLLxEN bit in RCC_CR. Refer to *Table 96* for an overview of available frequencies in this mode.

  If the PLL input clock (LSE or HSE) pulses are stopped or temporarily disturbed, the MSI PLL mode is automatically unlocked, and the MSI accuracy is consequently degraded. If enabled in RCC_CIER, an interrupt is generated. The MSI PLL mode with LSE unlock interrupt can wake up from Stop 0, Stop 1 and Stop 2 modes. To reconfigure the MSI in PLL mode, the MSIPLLxEN (x = 0,1) bit in RCC_CR must be cleared and set again.

  When MSIRC1 is used in PLL mode, the reached frequency can be selected thanks to MSIPLL1N[1:0] bitfield in the RCC_ICSR1. Those additional frequencies are useful for audio applications.

Table 96. MSIS and MSIK frequencies of MSIRC1 in PLL mode

MSI range	MSISDIV[1:0] or MSIKDIV[1:0]	PLL range MSIPLL1N[1:0]	MSIPLL1SEL = 0: LSE	MSIPLL1SEL = 1: HSE or HSE/2
Range 0: MSISSEL = 0 or MSIKSEL = 0	00: MSIRC0/1	XX	96.010 MHz	96.0 MHz
	01: MSIRC0/2	XX	48.005 MHz	48.0 MHz
	10: MSIRC0/4	XX	24.003 MHz	24.0 MHz
	11: MSIRC0/8	XX	12.001 MHz	12.0 MHz
Range 1: MSISSEL = 1 or MSIKSEL = 1	00: MSIRC1/1	0X	23.986 MHz	24.016 MHz
		10	22.577 MHz	22.581 MHz
		11	24.576 MHz	24.577 MHz
	01: MSIRC1/2	0X	11.993 MHz	12.008 MHz
		10	11.289 MHz	11.290 MHz
		11	12.288 MHz	12.289 MHz
	10: MSIRC1/4	0X	5.997 MHz	6.004 MHz
		10	5.644 MHz	5.645 MHz
		11	6.144 MHz	6.144 MHz
	11: MSIRC1/8	0X	2.998 MHz	3.002 MHz
		10	2.822 MHz	2.823 MHz
		11	3.072 MHz	3.072 MHz

- MSI PLL mode stabilization time

  When MSIPLLxEN (x = 0,1) = 1, the final accuracy after enabling the MSI (by writing MSISON = 1 or MSIKON = 1 or following a peripheral clock request in Stop mode) is reached after a stabilization time t_{STAB}(MSI) when the corresponding MSIPLLxFAST = 0. This stabilization time is needed even if the input clock (LSE or HSE) is kept enable. Refer to datasheet for t_{STAB}(MSI) value.

  If MSIPLLxEN = 1 with MSIPLLxFAST = 1 , the MSI oscillator is kept powered on when a request to switch it off is received (either by writing MSISON = 0 and MSIKON = 0, or because no peripheral requests this clock in Stop mode). In this case the MSI PLL mode accuracy is kept when the MSI is switched on again, providing that the t_{STAB}(MSI) stabilization time is reached before switching off the MSI. This mode can be used for autonomous peripherals requiring accuracy in Stop mode, with an extra consumption as the oscillator remains powered on, but gated off when disabled.

- Software calibration

  The MSIRCx (x = 0,1) oscillators frequency may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at an ambient temperature, T_A = 25 °C. After reset, the factory calibration value is loaded in the MSICALx[5:0] bits (x = 0,1) in RCC_ICSCR1. If the application is subject to voltage or temperature variations, this may affect the RC

oscillator speed. The MSIRCx frequency can be trimmed in the application by using the MSITRIMx[5:0] bits (x = 0,1) in RCC_ICSCR2.

Note: The final accuracy after applying the calibration value is reached after a stabilization time. This stabilization time is needed after reset of exiting Standby or Shutdown mode. It is also needed when switching from PLL mode to normal mode.

The hardware auto-calibration with LSE or HSE must not be used in conjunction with software calibration.

For more details on how to measure the MSI frequency variation, refer to *Internal/external clock measurement with TIM15/TIM16/TIM17*.

HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB and for random number generator (RNG) as well as SDMMC.

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE or an external signal to automatically and quickly adjust the oscillator frequency on-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency that is subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral, refer to *Section 11: Clock recovery system (CRS)*.

The HSI48RDY flag in RCC_CR indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in RCC_CR.

LSE clock

The LSE crystal is a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in RCC_BDCR. If the LSE is used by other peripherals of functions than RTC, TAMP, and LSECSS, the LSESYSEN bit must be also be set in RCC_BDCR (refer to *LSE when used by peripherals other than RTC/TAMP, and RCC functions*).

The crystal oscillator driving strength is configured using the LSEDRV[1:0] bits, according to crystal specification, to obtain the best compromise between robustness and short startup time on one side and low-power-consumption on the other side. The LSE drive must be programmed before enabling the LSE.

The LSERDY flag in RCC_BDCR indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

- External source (LSE bypass)

  In this mode, an external clock source must be provided. This mode is selected by setting the LSEBYP and LSEON bits in RCC_BDCR. The external clock signal (square, sinus or triangle) with ~50 % duty cycle, must drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO (see *Table 94: HSE/LSE clock sources*).

- LSE when used by peripherals other than RTC/TAMP, and RCC functions

  By default, when enabled, the LSE is sent only to RTC and TAMP (assuming that RTCSEL = 01).

  If the LSE is needed for other peripherals (such as peripheral clock or trigger source), or if the LSE is used by a RCC function (such as LSCO, MCO, MSI PLL mode), the sequence below must be done:

  a) Set the LSEON in RCC_BDCR, and wait the LSE clock ready bit (LSERDY = 1 in RCC_BDCR).

  b) Set the LSESYSEN bit in RCC_BDCR.

  c) Wait the LSESYS clock is ready (LSESYSRDY = 1 in RCC_BDCR).

  The LSE consumption is increased when LSESYSEN = 1.

LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby modes for the IWDG and RTC/TAMP. The clock frequency is either 32 kHz or 250 Hz, depending on the LSIPREDIV bit in RCC_CSR. Setting LSIPREDIV allows a lower consumption (refer to the electrical characteristics section of the datasheet for more details).

When the IWDG is enabled or when the RTC or TAMP is clocked by the LSI, the LSIPREDIV cannot be changed anymore.

The LSI RC can be switched on and off using the LSION bit in RCC_CSR.

The LSIRDY flag in RCC_CSR indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

System clock (SYSCLK) selection

Three different clock sources can be used to drive the system clock (SYSCLK):

- MSIS oscillator
- HSI16 oscillator
- HSE oscillator

The system clock maximum frequency is 96 MHz. After a system reset, the MSIS oscillator, at 12 MHz, is selected as system clock. When a clock source is used as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in the *RCC clock control register (RCC_CR)* indicate which clocks are ready and which clock is currently used as a system clock.

Table 97 gives the different bus frequencies depending on the product voltage range.

The EPOD (embedded power distribution) booster must be enabled when the system clock frequency is above 24 MHz in range 1 and range 2 (see *Dynamic voltage scaling management*). Before enabling this booster, its input clock must be selected and divided so that its frequency is between 3 and 16 MHz. The division factor is forced by hardware when the selected booster clock is MSIS. The booster must be enabled before entering Stop mode, with MSIS as the selected clock, if the wake-up clock is MSIS at 48 MHz.

Caution: The booster clock source must be kept enabled as long as the booster is enabled in Run and Sleep modes.

Table 97. Bus maximum frequency

Product voltage range		AHB1/AHB2/APB1/APB2/APB3
Range 1	EPOD booster enabled	96 MHz
	EPOD booster disabled	24 MHz
Range 2	EPOD booster enabled	48 MHz
	EPOD booster disabled	24 MHz

Clock source frequency versus voltage scaling

The table below gives the different clock source frequencies depending on the product voltage range.

Table 98. Clock source maximum frequency

Product voltage range	Clock frequency			
	MSIS MSIK	HSI16	HSI48	HSE
Range 1	All ranges	Allowed	Allowed	50 MHz
Range 2	Range 1 to 7	Allowed	Allowed	48 MHz

Clock security system (CSS)

The CSS can be activated by software. In this case, the clock detector is enabled after the HSE oscillator wake-up time, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled. A clock failure event is sent to some timers break input and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI). This allows the MCU to perform rescue operations. The CSSI is linked to the Cortex-M33 NMI (non-maskable interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSSF occurs and a NMI is automatically generated. The NMI is executed indefinitely unless the CSSF pending bit is cleared. As a consequence, in the NMI ISR, the user must clear the CSSF by setting the CSSC bit in RCC_CICR.

If the HSE oscillator is used as the system clock, a detected failure causes a switch of the system clock to the MSIS or the HSI16 oscillator depending on the STOPWUCK configuration in RCC_CFGR1, and the disabling of the HSE oscillator.

Clock security system on LSE

A clock security system on LSE can be activated by software writing the LSECSSON bit in RCC_BDCR. LSECSSON must be written after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after the RTC/TAMP clock has been selected by RTCSEL.

The CSS on LSE is working in all modes including VBAT. It works also under system reset (excluding power-on reset). If enabled in RCC_CIER, an interrupt is generated. The CSS on

LSE interrupt can wake up from all low-power modes. Refer to *Section 9: Power control (PWR)* for initialization sequence to wake-up from Stop 3 and Standby with CSS on LSE detection.

The clock security system on LSE detects when the LSE disappears or in case of over frequency. In addition, the glitches on LSE can be filtered by setting LSEGFON. LSEGFON must be written when the LSE is disabled (LSEON = 0 and LSERDY = 0).

If a failure is detected on the external 32 kHz oscillator (LSECSSD = 1), the LSE clock is no longer supplied to the RTC/TAMP but no hardware action is made to the registers. If the MSI was in PLL mode, this mode is disabled.

The CSS on LSE detection event is connected to the internal tamper 3 of the TAMP peripheral.

In case of CSS on LSE detection event (LSECSSD = 1 in RCC_BDCR), the software can decide either to keep on working with LSE, or to change RTC/TAMP clock source.

In order to enable again RTC and TAMP clocking with LSE clock, the software must clear the LSECSSON bit in RCC_BDCR. Disabling the CSS on LSE (LSECSSON = 0) also clears the LSE failure detection flag (LSECSSD), and allows LSE clock to be propagated to the RTC and TAMP.

In order to change the RTC/TAMP clock source, the software must first enable the target oscillator and wait for it to be ready, then change the RTCSEL[1:0]. Then the CSS on LSE should be disabled (LSECSSON = 0) as well as LSE oscillator (LSEON = 0).

ADC and DAC clocks

The ADC and DAC kernel clock source is selected thanks to ADCDACSEL[1:0] in RCC_CCIPR2. The selected clock source is divided thanks to ADCDACPRE[3:0] bitfield, from division by 1 to division by 512. The ADC clock ratio must be around 50 %. For this reason, the AHB clock, when selected as ADC clock, must not be divided with HPRE prescaler.

If the application requires that the ADC or DAC is precisely triggered by a TIMx timer without any uncertainty, the HCLK must be selected as ADC and DAC kernel clock source. The other clock sources are asynchronous to TIMx timers therefore an uncertainty of the trigger instant is added by the resynchronization between the two clock domains. The LPTIMx timers are also asynchronous.

The DAC requires an additional low-power clock (LSI or LSE) to operate in sample and hold mode, available in Stop mode. This clock is selected with DAC1SHSEL in RCC_CCIPR2.

RTC and TAMP clock

The RTCCLK clock source is used by RTC and TAMP, and can be either the HSE / 32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in RCC_BDCR. This selection cannot be modified without resetting the backup domain, except in case of CSS on LSE failure detection. The system must always be configured so as to get a PCLK frequency greater then or equal to the RTCCLK frequency for a proper operation of the RTC. The TAMP does not require any kernel clock if only the backup registers are used, with tampers in edge detection mode. All other tamper detection modes require a kernel clock (refer to *Section 44: Tamper and backup registers (TAMP)*).

The LSE is in the backup domain, whereas the LSI and HSE clock are not. Consequently:

- If LSE is selected as RTC and TAMP clock, these peripherals continue to work even if the V_{DD} supply is switched off, provided the V_{BAT} supply is maintained.
- If the LSI or HSE clock divided by a prescaler is used as the RTC or TAMP clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the internal voltage regulator is powered off (removing power from the core domain). Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

If the LSE is needed only for the RTC or TAMP, LSESYSEN must be kept at reset value to get the lowest consumption.

Timer clock

The timer clock frequencies are automatically defined by hardware.

There are two cases:

- If the APB prescaler equals 1, the timer clock frequencies are set to the APB domain frequency.
- Otherwise, they are set to twice (×2) the APB domain frequency.

Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced on and cannot be disabled. After the LSI oscillator temporization, the LSI 32 kHz clock is provided to the IWDG.

Clock-out capability

- **MCO**

  The microcontroller clock output (MCO) capability allows a clock to be output onto two external MCO and MCO2 pins. One of the following clock signals can be selected as MCO/MCO2 clock.

  – LSI
  – LSE
  – SYSCLK
  – HSI16
  – HSI48
  – HSE
  – MSIS
  – MSIK

  The selection is controlled by the MCOSEL[3:0] and MCO2SEL[3:0] bits in RCC_CFGR1. The selected clock can be divided with the MCOPRE[2:0] and MCO2PRE[2:0] field in RCC_CFGR1.

  The MCO clock output requires the corresponding alternate function selected on the MCO pin.

- **LSCO**

  Another output (LSCO) allows one of the low-speed clocks below to be output onto the external LSCO pin:

  – LSI

  – LSE

  This output remains available in all Stop, Standby, and Shutdown modes. This output is not available in V_{BAT} mode. The selection is controlled by the LSCOSEL bit and enabled with the LSCOEN in RCC_BDCR.

Internal/external clock measurement with TIM15/TIM16/TIM17

The frequency of all on-board clock sources can be indirectly measured by mean of the TIM15, TIM16, or TIM17 channel 1 input capture and LPTIM1 or LPTIM2 channel 2 input capture.

- HSI16 and MSI calibration using LSE

  The primary purpose of connecting the LSE to the channel 1 input capture of TIM15, TIM16, and TIM17, and to the channel 2 input capture of LPTIM1, is to be able to precisely measure the HSI16 and MSI system clocks (for this, either HSI16 or MSIS must be used as system clock source). The number of HSI16 (MSIS respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm), the internal clock frequency can be determined with the same resolution, and the source can be trimmed to compensate the manufacturing, process, temperature and/or voltage related frequency deviations.

  The four oscillators of MSI and HSI16 oscillator have dedicated user-accessible calibration bits for this purpose.

  The basic concept consists in providing a relative measurement (such as HSI16/LSE ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

  Note: When the LSE or HSE is available, the MSI can be automatically trimmed by LSE or HSE using the PLL mode.

- HSI16 and MSI calibration using HSE

  If the HSE is available, it can be used as system clock and the timer input capture must be connected either to MSI (divided by 1024 or by 4) or to HSI/256. The TIM16 and TIM17 channel 1 input capture, as well and the LPTIM2 input capture 2, are connected to the divided oscillator only when TIMICSEL[2:0] is different from 0xx in RCC_CCIPR1.

  Considering that the timers counter is 16-bit, and that the ratio between HSE and the input capture signal must be the highest possible, a division by 1024 must be selected when the MSIRC0, MSIRC1 or MSIRC2 is measured, and a division by 4 when the MSIRC4 is measured.

- LSI calibration

  The calibration of the LSI follows the same principle, but changing the reference clock. The LSI clock must be connected to the channel 1 input capture of the TIM16 or TIM17, or to the channel 2 input capture of the LPTIM1. Then defining the HSE as system

clock source, the number of its clock counts between consecutive edges of the LSI signal, provides a measure of the internal low-speed clock period.

The basic concept consists in providing a relative measurement (such as the HSE/LSI ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

Peripherals clock gating and autonomous mode

- Peripherals clock gating in Run mode

  Each peripheral clock can be enabled by the corresponding EN bit in the RCC_AHBxENR and RCC_APBxENR registers.

  When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.

  The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, there the clock is active after 2 cycles of the peripheral bus clock.

Caution: Just after enabling the clock for a peripheral, the software must wait for these 2 clock cycles before accessing the peripheral registers.

- Peripherals clock gating in Sleep mode

  When a peripheral is enabled, its clock can be automatically gated off when the device is in Sleep mode, by clearing the peripheral SLPEN bit in RCC_AHBxSLPENR and RCC_APBxSLPENR. Both EN and SLPEN bit of the peripheral must be set to keep the clock on in Sleep mode.

- Peripherals clock gating and autonomous mode in Stop 0/1/2 modes

  When a peripheral is enabled, its clock can be automatically gated off when the device is in Stop mode, by clearing the peripheral STPEN bit in RCC_AHBxSTPENR and RCC_APBxSTPENR. All EN, SLPEN and STPEN bits of the peripheral must be set to keep the clock on in Stop mode.

  The peripherals listed hereafter support autonomous mode in Stop 0 and Stop 1 modes: U(S)ARTx (x = 1, 3 to 5), LPUART1, SPIx (x = 1 to 3), I2Cx (x = 1 to 3), I3Cx (x = 1,2), LPTIMx (x = 1 to 4), ADF1, DAC1. Only LPUART1, I2C3, LPTIM1, LPTIM3, and LPTIM4 support autonomous mode in Stop 2 mode. These peripherals are able to generate a kernel clock request and a AHB/APB bus clock request when they need, in order to operate and update their status register even in Stop mode. Depending on the peripheral configuration, either a DMA request or an interrupt can be associated to the peripheral event.

  Upon an AHB or APB bus clock request from an autonomous peripheral, either MSIS or HSI16 oscillator is woken up, depending on the oscillator selected by STOPWUCK in RCC_CFGR1.

  If the autonomous peripheral is configured with DMA requests enabled, a data transfer is performed thanks to the AHB/APB clock. The bus clocks as well as the oscillator (HSI16 or MSIS) are automatically switched off as soon as the transfer is finished, if no other peripheral requests it. The device automatically goes back in Stop mode.

  If the autonomous peripheral is configured with interrupt enabled, the interrupt wakes up the device into Run mode.

  A peripheral autonomous mode is enabled in Stop 0, Stop 1, or Stop 2 modes if all peripheral EN, SLPEN and STPEN bits are set.

  If an autonomous peripheral requests its kernel clock in Stop 0, Stop 1, or Stop 2 mode, the internal oscillator (HSI16 or MSIK) is woken up if it was off, and the kernel clock is

propagated only to the peripheral requesting it. When the peripheral releases its kernel clock request, the HSI16 or MSI is switched off if no other peripheral requests it.

If an autonomous peripheral requests its AHB or APB bus clock in Stop 0, Stop 1 or Stop 2 mode, the internal oscillator (HSI16 or MSIS depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and the system clock is propagated to all peripherals configured with EN, SLPEN and STPEN bits. Therefore, the peripheral STPEN bit should be cleared to reduce consumption if the peripheral is not used in Stop mode.

Caution: The EN, SLPEN and STPEN bits of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop 0, Stop 1, and Stop 2 modes. This is not necessary when the peripheral wake-up interrupt is generated though the EXTI.

Note: MSIK or HSI16 can be forced to remain ON in Stop 0, Stop 1 or Stop 2 mode, by configuring MSIKERON or HSIKERON is the RCC_CR. In this case, the oscillator is propagated only to the kernel clock of the enabled autonomous peripherals with this oscillator selected as kernel clock. This allows the peripheral baudrates or conversion rates increase, as there is no need to wait for the oscillator wake-up time when the peripheral requests its kernel clock.

The LSE or LSI selected as peripheral kernel clock remains always ON in Stop modes.

10.2.4 RCC security and privilege functional description

RCC TrustZone security protection modes

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, the RCC is able to secure RCC configuration and status bits from being modified by nonsecure accesses.

This is configured through RCC_SECCFGR to prevent nonsecure access to read or modify the following features:

- HSE, HSE-CSS, HSI, MSI, LSI, LSE, LSE-CSS, LSCO, HSI48 configuration and status bits
- AHB and APB prescalers configuration and status bits
- System clock (SYSCLK) and ICLK source clock selection and status bits
- MCO/MCO2 clock output configuration and STOPWUCK and STOPKERWUCK bit
- Remove reset flag RMVF configuration

If SPRIV is set in RCC_PRIVCFGR, RCC_SECCFGR can be written only by secure and privileged access. If SPRIV is cleared in RCC_PRIVCFGR, RCC_SECCFGR can be written only by secure access, privileged or unprivileged.

RCC_SECCFGR can be read by secure, nonsecure, privileged and unprivileged access.

When a peripheral is configured as secure, its related clock, reset, clock source selection and clock enable during low-power modes control bits, are also secure in RCC_AHBxENR, RCC_APBxENR, RCC_AHBxSLPENR, RCC_APBxSLPENR, RCC_AHBxSTPENR, RCC_APBxSTPENR, RCC_CCIPR1, RCC_CCIPR2, RCC_CCIPR3, and RCC_BDCR.

BDRST in RCC_BDCR is secure when at least one function is secure in RTC or TAMP.

If several peripherals share same RCC resources, these resources are secure when at least one peripheral is configured as secured.

A peripheral is secure when:

- For securable peripherals by TZSC (TrustZone security controller), the SEC security bit corresponding to this peripheral is set in the GTZC TZSC secure configuration registers.
- For TrustZone-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.

Table 99 summarizes the RCC secured bits following the security configuration bit in RCC_SECCFGR.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and nonsecure bits:

- Secured bits: read and write operations are only allowed by a secure access. Nonsecure read returns 0 and write accesses are ignored. No illegal access event is generated.
- Nonsecure bits: no restriction. Read and write operations are allowed by both secure and nonsecure accesses.
- A nonsecure write access to RCC_SECCFGR is ignored and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in GTZC TZIC registers. RCC_SECCFGR can be read by secure or nonsecure access.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers are nonsecure. RCC_SECCFGR write accesses are ignored.

Table 99. RCC security configuration summary

Configuration bit in RCC_SECCFGR	Secured bits	Corresponding register
HSISEC	HSION, HSIKERON, HSIRDY	RCC_CR
	HSICAL[11:0], HSITRIM[4:0]	RCC_ICSCR3
	HSIRDYIE	RCC_CIER
	HSIRDYIF	RCC_CIFR
	HSIRDYC	RCC_CICR
HSESEC	HSEON, HSERDY, HSEBYP, HSECSSON, HSEEXT	RCC_CR
	HSERDYIE, HSECSSF	RCC_CIER
	HSERDYIF, HSECSSF	RCC_CIFR
	HSERDYC, HSECSSC	RCC_CICR

Table 99. RCC security configuration summary (continued)

Configuration bit in RCC_SECCFGR	Secured bits	Corresponding register
MSISEC	MSISON, MSIKERON, MSISRDY, MSPLL0EN, MSIPLL1EN, MSIPLL0RDY, MSIPLL1RDY, MSIKON, MSIKRDY, MSIPLL0FAST, MSIPLL1FAST	RCC_CR

RMVFSEC	RMVF	RCC_CSR

1. TRIM field of the HSI48 is located in CRS peripheral. Be sure to secure it using CRSSEC bit in GTZC TZSC secure configuration register 1.

RCC privilege protection modes

By default, after reset, all RCC registers can be read or written with both privileged and unprivileged access except RCC_PRIVCFGR that can be written with privileged access only. RCC_PRIVCFGR can be read by secure and nonsecure, privileged and unprivileged access.

The SPRIV bit in RCC_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all RCC secure functions (as defined by RCC_SECCFGR or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the SPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC secure bits is possible only with privileged access, including RCC_SECCFGR.
- The RCC secure bits can be read only with privileged access except RCC_SECCFGR and RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit in RCC_PRIVCFGR can be written with privileged access only, secure or nonsecure. This bit configures the privileged access of all RCC nonsecure functions (as defined by RCC_SECCFGR, or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the NSPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC nonsecure bits is possible only with privileged access.
- The RCC nonsecure bits can be read only with privileged access except RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

10.3 RCC in low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep mode stops the CPU clock. The memory interface clocks (flash memory, caches and all SRAM interfaces) can be stopped by software during Sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.

  Stop modes (Stop 0, Stop 1, Stop 2, Stop 3) stop all the clocks in the core domain and disable the HSI16, HSI48, MSI and HSE oscillators. However, HSI16 or MSI can be switched ON if the peripheral requests it for autonomous mode purpose (in Stop 0, Stop 1 and Stop 2 only), or to generate a wake-up interrupt (Stop 0, Stop 1 or Stop 2 only) (see *Peripherals clock gating and autonomous mode* for more details). LSI and LSE remain active in Stop modes.
- Standby and Shutdown modes stop all the clocks in the core domain and disable the HSI16, HSI48, MSI and HSE oscillators.

The CPU DeepSleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in DBGMCU_CR.

When exiting Stop modes (Stop 0, Stop 1, Stop 2, or Stop 3), the system clock is either MSIS or HSI16, depending on the software configuration of STOPWUCK in RCC_CFGR1. The frequency (range and user trim) of the MSIS and MSIK oscillators is the one configured before entering Stop mode, except if above 48 MHz. In this case, the MSIS or MSIK range is the 48 MHz range. The user trim of HSI16 is kept. If MSIRCx (x = 0,1) is in PLL mode before entering Stop mode with MSIPLLxFAST = 0, the PLL mode stabilization time must be waited for after wake-up even if the LSE was kept ON during the Stop mode. The PLL mode accuracy is kept after wake-up from Stop 0, Stop 1 or Stop 2 mode without stabilization time if MSIPLLxFAST = 1. The MSIPLLxFAST bit has no effect when exiting Stop 3 mode.

The other internal oscillator can be automatically woken up in addition to the one used by the system clock, in order to avoid waiting for the other oscillator wake-up time when the device is back in Run mode. This is done thanks to STOPKERWUCK in RCC_CFGR1.

When leaving Standby and Shutdown modes, the system clock is MSIS. The MSIS and MSIK frequency at wake-up from Standby mode is configured with MSISDIVS[1:0] and MSIKDIVS[1:0] in RCC_CSR, from 3 to 12 MHz. The MSI frequency at wake-up from Shutdown mode is 12 MHz. The user trim is lost.

If a flash memory programming operation is ongoing, Stop, Standby, or Shutdown mode entry is delayed until the flash memory interface access is finished. If an access to the APB domain is ongoing, Stop, Standby, or Shutdown mode entry is delayed until the APB access is finished. If an autonomous peripheral generates a system clock request, Stop, Standby or Shutdown mode entry is delayed until the system clock request is released.

10.4 RCC interrupts

The following table summarizes the interrupt sources and the way to control them.

Table 100. Interrupt sources and control

Interrupt event flag	Description	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop modes	Exit Standby, Shutdown modes
Interrupt vector: RCC						
LSIRDYF	LSI ready	LSIRDYIE = 0 LSISEC = 0	LSIRDYC = 1	Yes	No	No
LSERDYF	LSE ready	LSERDYIE = 0 LSESEC = 0	LSERDYC = 1	Yes	No	No
HSIDRYF	HSI ready	HSIDRYIE = 0 HSISEC = 0	HSIRDYC = 1	Yes	No	No
HSERDYF	HSE ready	HSERDYIE = 0 HSESEC = 0	HSERDYC = 1	Yes	No	No
MSISRDYF	MSIS ready	MSISRDYIE = 0 MSISEC = 0	MSISRDYC = 1	Yes	No	No
MSIKRDYF	MSIK ready	MSIKRDYIE = 0 MSISEC = 0	MSIKRDYC = 1	Yes	No	No

Table 100. Interrupt sources and control (continued)

Interrupt event flag	Description	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop modes	Exit Standby, Shutdown modes
MSIPLL0RDYF	MSIRC0 PLL mode ready	MSIPLL0RDYIE = 0 MSISEC = 0	MSIPLL0RDYC = 1	Yes	No	No
MSIPLL1RDYF	MSIRC1 PLL mode ready	MSIPLL1RDYIE = 0 MSISEC = 0	MSIPLL1RDYC = 1	Yes	No	No
MSIPLLUF	MSI PLL mode with LSE unlock	MSIPLLUIE = 0 MSISEC = 0	MSIPLLUC = 1	Yes	Yes(1)	No
MSIPLLHSUF	MSI PLL mode with HSE unlock	MSIPLLHSUIE = 0 MSISEC = 0	MSIPLLHSUC = 1	Yes	No	No
LSECSSF	LSE clock security system detection	LSECSSIE = 0 LSESEC = 0	LSECSSC = 1	Yes	Yes	Yes
HSI48RDYF	HSI48 ready	HSI48RDYIE = 0 HSI48SEC = 0	HSI48RDYC = 1	Yes	No	No
Interrupt vector: RCC_S(2)						
LSIRDYF	LSI ready	LSIRDYIE = 1 LSISEC = 1	LSIRDYC = 1	Yes	No	No
LSERDYF	LSE ready	LSERDYIE = 1 LSESEC = 1	LSERDYC = 1	Yes	No	No
HSIDRYF	HSI ready	HSIDRYIE = 1 HSISEC = 1	HSIRDYC = 1	Yes	No	No
HSERDYF	HSE ready	HSERDYIE = 1 HSESEC = 1	HSERDYC = 1	Yes	No	No
MSISRDYF	MSIS ready	MSISRDYIE = 1 MSISEC = 1	MSISRDYC = 1	Yes	No	No
MSIKRDYF	MSIK ready	MSIKRDYIE = 1 MSISEC = 1	MSIKRDYC = 1	Yes	No	No
MSIPLL0RDYF	MSIRC0 PLL mode ready	MSIPLL0RDYIE = 1 MSISEC = 1	MSIPLL0RDYC = 1	Yes	No	No
MSIPLL1RDYF	MSIRC1 PLL mode ready	MSIPLL1RDYIE = 1 MSISEC = 1	MSIPLL1RDYC = 1	Yes	No	No
MSIPLLUF	MSI PLL mode with LSE unlock	MSIPLLUIE = 1 MSISEC = 1	MSIPLLUC = 1	Yes	Yes	No
MSIPLLHSUF	MSI PLL mode with HSE unlock	MSIPLLHSUIE = 1 MSISEC = 1	MSIPLLHSUC = 1	Yes	No	No
LSECSSF	LSE clock security system detection	LSECSSIE = 1 LSESEC = 1	LSECSSC = 1	Yes	Yes	Yes
HSI48RDYF	HSI48 ready	HSI48RDYIE = 1 HSI48SEC = 1	HSI48RDYC = 1	Yes	No	No
Interrupt vector: NMI						
HSECSSF	HSE CSS failure	- (3)	HSECSSC = 1	Yes	No	No

1. Except Stop 3 mode
2. The RCC secure interrupt vector is used only when TrustZone is enabled.
3. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).

10.5 RCC registers

10.5.1 RCC clock control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 001D

HSEBYP and HSEEXT are cleared upon power-on reset. They are not affected upon other types of reset.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSEEXT	HSECSSON	HSEBYP	HSERDY	HSEON
											rw	rs	rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSI48RDY	HSI48ON	HSIRDY	HSIKERON	HSION	MSIPLL0RDY	MSIPLL1RDY	MSIPLL0FAST	MSIPLL1FAST	MSIPLL0EN	MSIPLL1EN	MSIKRDY	MSIKON	MSISRDY	MSIKERON	MSISON
r	rw	r	rw	rw	r	r	rw	rw	rw	rw	r	rw	r	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: HSE external clock bypass mode

Used to select the external clock mode in bypass mode. External clock mode must be configured with HSEON bit to be used by the device. This bit can be written only if the HSE oscillator is disabled. This bit is active only if the HSE bypass mode is enabled.

0: External HSE clock analog mode

1: External HSE clock digital mode (through I/O Schmitt trigger)

Bit 19 **HSECSSON**: Clock security system enable

Used to enable the clock security system. When HSECSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.

0: Clock security system OFF (clock detector OFF)

1: Clock security system ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18 **HSEBYP**: HSE crystal oscillator bypass

Used to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled (HSEON = 0 and HSERDY = 0).

0: HSE crystal oscillator not bypassed

1: HSE crystal oscillator bypassed with external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE oscillator not ready

1: HSE oscillator ready

Note: Once the HSEON bit is cleared, HSERDY goes low after six HSE clock cycles.

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software. Cleared by hardware to stop the HSE oscillator when entering Stop, Standby, or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as system clock.

0: HSE oscillator OFF

1: HSE oscillator ON

Bit 15 **HSI48RDY**: HSI48 clock ready flag

Set by hardware to indicate that the HSI48 oscillator is stable. This bit is set only when HSI48 is enabled by software by setting HSI48ON.

0: HSI48 oscillator not ready

1: HSI48 oscillator ready

Bit 14 **HSI48ON**: HSI48 clock enable

Set and cleared by software. Cleared by hardware to stop the HSI48 when entering in Stop, Standby, or Shutdown mode.

0: HSI48 oscillator OFF

1: HSI48 oscillator ON

Bit 13 **HSIRDY**: HSI16 clock ready flag

Set by hardware to indicate that HSI16 oscillator is stable after HSION is set.

0: HSI16 oscillator not ready

1: HSI16 oscillator ready

Note: When the HSI is enabled due to HSIKERON or to peripheral clock request, the HSIRDY remains cleared. Once the HSION bit is cleared, HSIRDY goes low after six HSI16 clock cycles.

Bit 12 **HSIKERON**: HSI16 enable for some peripheral kernels

Used to force HSI16 ON even in Stop modes. Keeping the HSI16 ON in Stop mode allows the communication speed not to be reduced by the HSI16 startup time. This bit has no effect on HSION value (refer to *Peripherals clock gating and autonomous mode* for more details). The HSIKERON must be configured at 0 before entering Stop 3 mode.

0: No effect on HSI16 oscillator

1: HSI16 oscillator forced ON even in Stop mode

Bit 11 **HSION**: HSI16 clock enable

Set and cleared by software. Cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby, or Shutdown mode.

Set by hardware to force the HSI16 oscillator ON when STOPWUCK = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator.

This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.

0: HSI16 oscillator OFF

1: HSI16 oscillator ON

Bit 10 **MSIPLL0RDY**: MSIRC0 PLL mode ready flag

Set by hardware to indicate that the MSIRC0 PLL mode is locked, when the PLL mode is enabled (MSIPLL0EN = 1). This bit is cleared when the PLL mode is disabled (MSIPLL0EN = 0) or when the MSI is disabled (MSISON = MSIKON = 0).

0: MSIRC0 PLL mode is not ready

1: MSIRC0 PLL mode is ready

Bit 9 **MSIPLL1RDY**: MSIRC1 PLL mode ready flag

Set by hardware to indicate that the MSIRC1 PLL mode is locked, when the PLL mode is enabled (MSIPLL1EN = 1). This bit is cleared when the PLL mode is disabled (MSIPLL1EN = 0) or when the MSI is disabled (MSISON = MSIKON = 0).

0: MSIRC1 PLL mode is not ready

1: MSIRC1 PLL mode is ready

Bit 8 **MSIPLL0FAST**: MSIRC0 PLL mode fast startup

This bit is used only if PLL mode is selected (MSIPLL0EN = 1).

The fast startup feature is not active the first time the PLL mode is selected. The fast startup is active when the MSIRC0 in PLL mode returns from switch off.

0: MSIRC0 PLL normal startup

1: MSIRC0 PLL fast startup

Bit 7 **MSIPLL1FAST**: MSIRC1 PLL mode fast startup

This bit is used only if PLL mode is selected (MSIPLL1EN = 1).

The fast startup feature is not active the first time the PLL mode is selected. The fast startup is active when the MSIRC1 in PLL mode returns from switch off.

0: MSIRC1 PLL normal startup

1: MSIRC1 PLL fast startup

Bit 6 **MSIPLL0EN**: MSIRC0 PLL mode enable

Either MSIS or MSIK, with MSIRC0 selected, must be enabled and ready before enabling MSIRC0 PLL mode.

When MSIPLL0SEL = 0, MSIPLL0EN must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware). A hardware protection prevents from enabling MSIPLL0EN if LSE is not ready. This bit is cleared by hardware when LSE is disabled (LSEON = 0), or when the CSS on LSE detects a LSE failure (see RCC_CR).

When MSIPLL0SEL = 1, MSIPLL0EN must be enabled after HSE is enabled (HSEON enabled) and ready (HSERDY set by hardware). A hardware protection prevents from enabling MSIPLL0EN if HSE is not ready, and MSIPLL0SEL is ignored. This bit is cleared by hardware when HSE is disabled (HSEON = 0) or when the CSS on HSE detects a HSE failure.

0: MSIRC0 PLL mode disabled

1: MSIRC0 PLL mode enabled

Bit 5 **MSIPLL1EN**: MSIRC1 PLL mode enable

Either MSIS or MSIK, with MSIRC1 selected, must be enabled and ready before enabling MSIRC1 PLL mode.

When MSIPLL1SEL = 0, MSIPLL1EN must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware). A hardware protection prevents from enabling MSIPLL1EN if LSE is not ready. This bit is cleared by hardware when LSE is disabled (LSEON = 0) or when the CSS on LSE detects a LSE failure (see RCC_CSR).

When MSIPLL1SEL = 1, MSIPLL1EN must be enabled after HSE is enabled (HSEON enabled) and ready (HSERDY set by hardware). A hardware protection prevents from enabling MSIPLL1EN if HSE is not ready, and MSIPLL1SEL is ignored. This bit is cleared by hardware when HSE is disabled (HSEON = 0) or when the CSS on HSE detects a HSE failure.

0: MSIRC1 PLL mode disabled

1: MSIRC1 PLL mode enabled

Bit 4 **MSIKRDY**: MSIK clock ready flag

Set by hardware to indicate that the MSIK is stable.

0: MSIK (MSI kernel) oscillator not ready

1: MSIK (MSI kernel) oscillator ready

Note: Once the MSIKON bit is cleared, MSIKRDY goes low after six MSIK oscillator clock cycles.

Bit 3 **MSIKON**: MSIK clock enable

Set and cleared by software. Cleared by hardware to stop the MSIK when entering Stop, Standby, or Shutdown mode. Set by hardware to force the MSIK oscillator ON when exiting Standby or Shutdown mode. Set by hardware to force the MSIK oscillator ON when STOPWUCK = 0 or STOPKERWUCK = 0 when exiting Stop modes, or in case of a failure of the HSE oscillator.

0: MSIK (MSI kernel) oscillator disabled

1: MSIK (MSI kernel) oscillator enabled

Bit 2 **MSISRDY**: MSIS clock ready flag

Set by hardware to indicate that the MSIS oscillator is stable after MSISON is set.

0: MSIS (MSI system) oscillator not ready

1: MSIS (MSI system) oscillator ready

Note: Once the MSISON bit is cleared, MSISRDY goes low after six MSIS clock cycles.

Bit 1 **MSIKERON:** MSI enable for some peripheral kernels

This bit is used to force MSI ON even in Stop mode. Keeping the MSI ON in Stop mode allows the communication speed not to be reduced by the MSI startup time. This bit has no effect on MSISON and MSIKON values (see *Peripherals clock gating and autonomous mode* for more details). MSIKERON must be configured at 0 before entering Stop 3 mode.

0: No effect on MSI oscillator

1: MSI oscillator forced ON even in Stop mode.

Bit 0 **MSISON**: MSIS clock enable

Set and cleared by software. Cleared by hardware to stop the MSIS oscillator when entering Stop, Standby, or Shutdown mode. Set by hardware to force the MSIS oscillator ON when exiting Standby or Shutdown mode. Set by hardware to force the MSIS oscillator ON when STOPWUCK = 0 when exiting Stop modes, or in case of a failure of the HSE oscillator.

Set by hardware when used directly or indirectly as system clock.

0: MSIS (MSI system) oscillator OFF

1: MSIS (MSI system) oscillator ON

10.5.2 RCC internal clock source calibration register 1 (RCC_ICSCR1)

Address offset: 0x008

Reset value: 0xB400 0XXX

X is factory-programmed.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSISSEL	MSISDIV[1:0]		MSIKSEL	MSIKDIV[1:0]		MSIPLL1N[1:0]		MSIRGSEL	MSIBIAS	MSIPLL0SEL	MSIPLL1SEL	MSIHSINDIV	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rs	rw	rw	rw	rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	MSICAL0[5:0]						MSICAL1[5:0]					
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **MSISSEL**: MSIS clock source selection

These bits are configured by software to select the RC oscillator used to generate MSIS clock when MSIRGSEL is set.

0: MSIRC0 (96 MHz) is selected as source to generate MSIS.

1: MSIRC1 (24 MHz) is selected as source to generate MSIS.

Note: MSISSEL can be modified when MSIS is OFF (MSISON = 0) or when MSIS is ready (MSISRDY = 1). MSISSEL must not be modified when MSIS is ON and NOT ready (MSISON = 1 and MSISRDY = 0). MSISSEL is kept when the device wakes up from Stop mode.

Bits 30:29 **MSISDIV[1:0]**: MSIS oscillator division

These bits are configured by software to choose the frequency of MSIS oscillator when MSIRGSEL is set.

Condition: MSISSEL bit in RCC_ICSCR1 = 0

00: MSIRC0/1 is selected for MSIS (range 0 around 96 MHz).

01: MSIRC0/2 is selected for MSIS (range 1 around 48 MHz).

10: MSIRC0/4 is selected for MSIS (range 2 around 24 MHz).

11: MSIRC0/8 is selected for MSIS (range 3 around 12 MHz).

Condition: MSISSEL bit in RCC_ICSCR1 = 1

00: MSIRC1/1 is selected for MSIS (range 4 around 24 MHz).

01: MSIRC1/2 is selected for MSIS (range 5 around 12 MHz).

10: MSIRC1/4 is selected for MSIS (range 6 around 6 MHz).

11: MSIRC1/8 is selected for MSIS (range 7 around 3 MHz).

Note: MSISDIV can be modified when MSIS is OFF (MSISON = 0) or when MSIS is ready (MSISRDY = 1). MSISDIV must NOT be modified when MSIS is ON and NOT ready (MSISON = 1 and MSISRDY = 0). MSISDIV is kept when the device wakes up from Stop mode, except when the MSIS range is above 48 MHz. In this case, MSISDIV is changed by hardware into range 1 (48 MHz).The frequencies slightly differ in PLL mode (refer to datasheet for more information).

Bit 28 **MSIKSEL**: MSIK clock source selection

These bits are configured by software to select the RC oscillator used to generate MSIK clock when MSIRGSEL is set.

0: MSIRC0 (96 MHz) is selected as source to generate MSIK.

1: MSIRC1 (24 MHz) is selected as source to generate MSIK.

Note: MSIKSEL can be modified when MSIK is OFF (MSIKON = 0) or when MSIK is ready (MSIKRDY = 1). MSIKSEL must not be modified when MSIK is ON and NOT ready (MSIKON = 1 and MSIKRDY = 0). MSIKSEL is kept when the device wakes up from Stop mode.

Bits 27:26 **MSIKDIV[1:0]**: MSIK oscillator division

These bits are configured by software to choose the frequency of MSIK oscillator when MSIRGSEL is set.

Condition: MSIKSEL bit in RCC_ICSCR1 = 0

00: MSIRC0/1 is selected for MSIK (range 0 around 96 MHz).

01: MSIRC0/2 is selected for MSIK (range 1 around 48 MHz).

10: MSIRC0/4 is selected for MSIK (range 2 around 24 MHz).

11: MSIRC0/8 is selected for MSIK (range 3 around 12 MHz).

Condition: MSIKSEL bit in RCC_ICSCR1 = 1

00: MSIRC1/1 is selected for MSIK (range 4 around 24 MHz).

01: MSIRC1/2 is selected for MSIK (range 5 around 12 MHz).

10: MSIRC1/4 is selected for MSIK (range 6 around 6 MHz.)

11: MSIRC1/8 is selected for MSIK (range 7 around 3 MHz).

Note: MSIKDIV can be modified when MSIK is OFF (MSIKON = 0) or when MSIK is ready (MSIKRDY = 1). MSIKDIV must NOT be modified when MSIK is ON and NOT ready (MSIKON = 1 and MSIKRDY = 0). MSIKDIV is kept when the device wakes up from Stop mode, except when the MSIK range is above 48 MHz. In this case MSIKDIV is changed by hardware into range 1 (48 MHz). The frequencies slightly differ in PLL mode (refer to datasheet for more information).

Bits 25:24 **MSIPLL1N[1:0]**: MSIRC1 PLL mode with LSE multiplication factor

These bits select the frequency of MSIRC1 in PLL mode, impacting range 4, 5, 6 and 7 frequencies. These bits have no effect when the PLL mode is disabled.

Note: Refer to Table 95: MSIS and MSIK ranges per internal MSIRCs (PLL mode disabled) for MSIS/MSIK clock output depends on input and configuration.

Bit 23 **MSIRGSEL**: MSI clock range selection

Set by software to select the MSIS/MSIK frequency range, using MSISSEL/MSIKSEL and MSISDIV[1:0]/MSIKDIV[1:0] bitfields. Writing 0 has no effect.

After exiting Standby or Shutdown mode, or after a reset, this bit is at 0, and the MSIS and MSIK ranges are provided by MSISDIVS[1:0] and MSIKDIVS[1:0] in RCC_CSR.

0: MSIS/MSIK ranges provided by MSISDIVS[1:0] and MSIKDIVS[1:0] in RCC_CSR

1: MSIS/MSIK ranges provided by MSISDIV[1:0] and MSIKDIV[1:0] in RCC_ICSCR1

Bit 22 **MSIBIAS**: MSI bias mode selection

By default, the MSI bias (for both MSIS and MSIK) is in continuous mode in order to maintain the output clocks accuracy. Setting this bit reduces the MSI consumption when the device is in Stop 1 or Stop 2 mode, or when the regulator is in range 2, but it decreases the MSI accuracy

0: MSI bias continuous mode (clock accuracy fast settling time)

1: MSI bias sampling mode when the device is in Stop 1 or Stop 2 mode, or when the regulator is in range 2

Bit 21 **MSIPLL0SEL**: MSIRC0 PLL mode input clock selection

LSE or HSE must be enabled and ready before selecting this oscillator as MSIRC0 input clock.

0: LSE is used as MSIRC0 input clock when PLL mode is selected.

1: HSE or HSE/2 is used as MSIRC0 input clock when PLL mode is selected.

Bit 20 **MSIPLL1SEL**: MSIRC1 PLL mode input clock selection

LSE or HSE must be enabled and ready before selecting this oscillator as MSIRC1 input clock.

0: LSE is used as MSIRC1 input clock when PLL mode is selected.

1: HSE or HSE/2 is used as MSIRC1 input clock when PLL mode is selected.

Bit 19 **MSIHSINDIV**: MSIRCx (x = 0, 1) PLL mode HSE input division

This bit is used to divide the HSE input clock when used by MSIRCx (x = 0, 1) in PLL mode. MSIRCx high-speed input clock must be 16 MHz.

0: HSE (16 MHz) is used as MSI input clock when PLL mode with high-speed clock is selected.

1: HSE (32 MHz)/2 is used as MSI input clock when PLL mode with high-speed clock is selected.

Bits 18:12 Reserved, must be kept at reset value.

Bits 11:6 **MSICAL0[5:0]**: MSIRC0 clock calibration for MSI ranges 0 to 3

These bits are initialized at startup with the factory-programmed MSIRC0 calibration trim value for ranges 0 to 3. When MSITRIM0 is written, MSICAL0 is updated with the sum of MSITRIM0[5:0] and the factory-programmed calibration trim value MSIRC0[5:0].

There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

Bits 5:0 **MSICAL1[5:0]**: MSIRC1 clock calibration for MSI ranges 4 to 7

These bits are initialized at startup with the factory-programmed MSIRC1 calibration trim value for ranges 4 to 7. When MSITRIM1 is written, MSICAL1 is updated with the sum of MSITRIM1[5:0] and the factory-programmed calibration trim value MSIRC1[5:0].

There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

10.5.3 RCC internal clock source calibration register 2 (RCC_ICSCR2)

Address offset: 0x00C

Reset value: 0x0000 0820

Access: no wait state; word, half-word, and byte access

Note: The hardware auto calibration (PLL mode) must not be used in conjunction with software calibration

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:6 **MSITRIM0[5:0]**: MSIRC0 clock trimming for ranges 0 to 3

These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC0[5:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 5:0 **MSITRIM1[5:0]**: MSIRC1 clock trimming for ranges 4 to 7

These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC1[5:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

10.5.4 RCC internal clock source calibration register 3 (RCC_ICSCR3)

Address offset: 0x010

Reset value: 0x0010 0XXX

X is factory-programmed.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **HSITRIM[4:0]:** HSI clock trimming

These bits provide an additional user-programmable trimming value. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the HSI.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

These bits are initialized at startup with the factory-programmed HSI calibration trim value.

10.5.5 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x014

Reset value: 0x0000 0XXX

X is factory-programmed.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[8:0]								
							r	r	r	r	r	r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **HSI48CAL[8:0]**: HSI48 clock calibration

These bits are initialized at startup with the factory-programmed HSI48 calibration trim value.

10.5.6 RCC clock configuration register 1 (RCC_CFGR1)

Address offset: 0x01C

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2; word, half-word, and byte access

1 or 2 wait states are inserted only if the access occurs during clock source switch.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	MCOPRE[2:0]			MCOSEL[3:0]				Res.	MCO2PRE[2:0]			MCO2SEL[3:0]

										rw	rw	r	r	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **MCOPRE[2:0]**: Microcontroller clock output prescaler

This prescaler must be configured before MCO output is enabled.

000: MCO divided by 1
001: MCO divided by 2
010: MCO divided by 4
011: MCO divided by 8
100: MCO divided by 16
101: MCO divided by 32
110: MCO divided by 64
111: MCO divided by 128

Bits 27:24 **MCOSEL[3:0]**: Microcontroller clock output

Set and cleared by software.

0000: MCO output disabled, no clock on MCO
0001: SYSCLK system clock selected
0010: MSIS clock selected
0011: HSI16 clock selected
0100: HSE clock selected
0101: LSI clock selected
0110: LSE clock selected
0111: HSI48 clock selected
1000: MSIK clock selected
Others: Reserved

Note: This clock output may have some truncated cycles at startup or during MCO clock source switching.

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **MCO2PRE[2:0]**: Microcontroller clock output 2 prescaler
This prescaler must be configured before MCO2 output is enabled.
000: MCO2 divided by 1
001: MCO2 divided by 2
010: MCO2 divided by 4
011: MCO2 divided by 8
100: MCO2 divided by 16
101: MCO2 divided by 32
110: MCO2 divided by 64
111: MCO2 divided by 128

Bits 19:16 **MCO2SEL[3:0]**: Microcontroller clock output 2
0000: MCO2 output disabled, no clock on MCO2
0001: SYSCLK system clock selected
0010: MSIS clock selected
0011: HSI16 clock selected
0100: HSE clock selected
0101: LSI clock selected
0110: LSE clock selected
0111: HSI48 clock selected
1000: MSIK clock selected
Others: Reserved

Note: This clock output may have some truncated cycles at startup or during MCO clock source switching.

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **STOPKERWUCK**: Wake-up from Stop kernel clock automatic enable selection
This bit is used to enable automatically another oscillator than the one used as wake-up from Stop system clock. This helps to save its wake-up time when this oscillator is needed as peripheral independent kernel clock.
0: MSIK oscillator automatically enabled when exiting Stop mode or when a CSS on HSE event occurs
1: HSI16 oscillator automatically enabled when exiting Stop mode or when a CSS on HSE event occurs

Note: STOPKERWUCK must be programmed with the same value than STOPWUCK to avoid the other oscillator power-on after CSS event or Stop mode exit.

Bit 4 **STOPWUCK**: Wake-up from Stop and CSS backup clock selection
This bit is used to select the system clock used when exiting Stop mode. The selected clock is also used as emergency clock for the clock security system on HSE.
0: MSIS oscillator selected as wake-up from stop clock and CSS backup clock
1: HSI16 oscillator selected as wake-up from stop clock and CSS backup clock

Note: STOPWUCK must not be modified when the CSS is enabled by HSECSSON bit in RCC_CR and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW = 10). STOPKERWUCK must be programmed with the same value than STOPWUCK to avoid the other oscillator power-on after CSS event or Stop mode exit.

Bits 3:2 **SWS[1:0]**: System clock switch status
Set and cleared by hardware to indicate which clock source is used as system clock.
00: MSIS oscillator used as system clock
01: HSI16 oscillator used as system clock
10: HSE used as system clock
11: Reserved

Bits 1:0 **SW[1:0]**: System clock switch

These bits are used to select system clock source (SYSCLK). Configured by hardware to force MSIS oscillator selection when exiting Standby or Shutdown mode. Configured by hardware to force MSIS or HSI16 oscillator selection when exiting Stop mode, or in case of HSE oscillator failure, depending on STOPWUCK value.

00: MSIS selected as system clock

01: HSI16 selected as system clock

10: HSE selected as system clock

11: Reserved

10.5.7 RCC clock configuration register 2 (RCC_CFGR2)

Address offset: 0x020

Reset value: 0x0000 0000

Access: word, half-word, and byte access

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is ongoing.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	PPRE2[2:0]			Res.	PPRE1[2:0]			HPRE[3:0]			
					rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE2[2:0]**: APB2 prescaler

These bits are used to configure the division factor of the APB2 clock (PCLK2).

000-011: PCLK2 = HCLK not divided

100: PCLK2 = HCLK divided by 2

101: PCLK2 = HCLK divided by 4

110: PCLK2 = HCLK divided by 8

111: PCLK2 = HCLK divided by 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE1[2:0]**: APB1 prescaler

These bits are used to configure the division factor of the APB1 clock (PCLK1).

000-011: PCLK1 = HCLK not divided

100: PCLK1 = HCLK divided by 2

101: PCLK1 = HCLK divided by 4

110: PCLK1 = HCLK divided by 8

111: PCLK1 = HCLK divided by 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler

These bits are used to configure the division factor of the AHB clock (HCLK). Depending on the device voltage range, the software must set these bits correctly to ensure that the system frequency does not exceed the maximum allowed frequency (for more details, refer to *Table 97: Bus maximum frequency*). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value is taken into account.

0000-0111: HCLK = SYSCLK not divided
1000: HCLK = SYSCLK divided by 2
1001: HCLK = SYSCLK divided by 4
1010: HCLK = SYSCLK divided by 8
1011: HCLK = SYSCLK divided by 16
1100: HCLK = SYSCLK divided by 64
1101: HCLK = SYSCLK divided by 128
1110: HCLK = SYSCLK divided by 256
1111: HCLK = SYSCLK divided by 512

10.5.8 RCC clock configuration register 3 (RCC_CFGR3)

Address offset: 0x024

Reset value: 0x0000 0000

Access: word, half-word, and byte access

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is ongoing.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw	rw	rw				

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE3[2:0]**: APB3 prescaler

These bits are used to configure the division factor of the APB3 clock (PCLK3).

000-011: PCLK3 = HCLK not divided
100: PCLK3 = HCLK divided by 2
101: PCLK3 = HCLK divided by 4
110: PCLK3 = HCLK divided by 8
111: PCLK3 = HCLK divided by 16

Bits 3:0 Reserved, must be kept at reset value.

10.5.9 RCC clock configuration register 4 (RCC_CFGR4)

Address offset: 0x028

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BOOSTDIV[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOSTSEL[1:0]	
rw	rw	rw	rw											rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **BOOSTDIV[3:0]**: EPOD booster input clock prescaler

These bits are used to configure the division factor for the EPOD booster input clock, when it is HSI16 or HSE. The division factor is forced by hardware when the EPOD booster input clock is MSIS. In this case, these bits are read only. The EPOD booster input frequency is BOOSTSEL oscillator/BOOSTDIV, and must be between 3 and 16 MHz (see *Section 10.1: RCC introduction*).

0000: Divided by 1 (bypass)
0001: Divided by 2
0010: Divided by 4
0011: Divided by 6
0100: Divided by 8
0101: Divided by 10
0110: Divided by 12
0111: Divided by 14
1000: Divided by 16
Others: Reserved

Bits 11:2 Reserved, must be kept at reset value.

Bits 1:0 **BOOSTSEL[1:0]**: EPOD booster input clock source selection

These bits are used to selected to EPOD booster input clock source oscillator. The booster clock source must be enabled and configured before enabling the booster. BOOSTSEL must be kept at 00 to save power when the booster is disabled.

00: No clock
01: MSIS selected as EPOD booster clock source
10: HSI16 selected as EPOD booster clock source
11: HSE selected as EPOD booster clock source

10.5.10 RCC clock interrupt enable register (RCC_CIER)

Address offset: 0x050

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LSECSSIE**: LSE clock security system interrupt enable
0: LSE CSS interrupt disabled
1: LSE CSS interrupt enabled

Bit 11 **MSIKRDYIE**: MSIK ready interrupt enable
0: MSIK ready interrupt disabled
1: MSIK ready interrupt enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **MSIPLLHSUIE**: MSI PLL mode with HSE unlock interrupt enable
0: MSI PLL mode with HSE unlock interrupt disabled
1: MSI PLL mode with HSE unlock interrupt enabled

Bit 8 **MSIPLLUIE**: MSI PLL mode with LSE unlock interrupt enable
0: MSI PLL mode with LSE unlock interrupt disabled
1: MSI PLL mode with LSE unlock interrupt enabled

Bit 7 **MSIPLL0RDYIE**: MSIRC0 PLL mode ready interrupt enable
0: MSIRC0 PLL mode lock interrupt disabled
1: MSIRC0 PLL mode lock interrupt enabled

Bit 6 **MSIPLL1RDYIE**: MSIRC1 PLL mode ready interrupt enable
0: MSIRC1 PLL mode lock interrupt disabled
1: MSIRC1 PLL mode lock interrupt enabled

Bit 5 **HSI48RDYIE**: HSI48 ready interrupt enable
0: HSI48 ready interrupt disabled
1: HSI48 ready interrupt enabled

Bit 4 **HSERDYIE**: HSE ready interrupt enable
0: HSE ready interrupt disabled
1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI16 ready interrupt enable
0: HSI16 ready interrupt disabled
1: HSI16 ready interrupt enabled

Bit 2 **MSISRDYIE**: MSIS ready interrupt enable
0: MSIS ready interrupt disabled
1: MSIS ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
0: LSE ready interrupt disabled
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
0: LSI ready interrupt disabled
1: LSI ready interrupt enabled

10.5.11 RCC clock interrupt flag register (RCC_CIFR)

Address offset: 0x054

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LSECSSF	MSIKRDYF	CSSF	MSIPLLHSUF	MSIPLLUF	MSIPLL0RDYF	MSIPLL1RDYF	HSI48RDYF	HSERDYF	HSIRDYF	MSISRDYF	LSERDYF	LSIRDYF
			r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LSECSSF**: LSE clock security system interrupt flag
Set by hardware when a failure is detected on LSE and LSECSSIE is set. Cleared by software setting the LSECSSC bit.
0: No LSE clock security interrupt
1: LSE clock security interrupt

Bit 11 **MSIKRDYF**: MSIK ready interrupt flag
Set by hardware when the MSIK clock becomes stable and MSIKRDYIE is set. Cleared by software setting the MSIKRDYC bit.
0: No MSIK oscillator clock ready interrupt
1: MSIK oscillator clock ready interrupt

Bit 10 **CSSF**: Clock security system interrupt flag
Set by hardware when a failure is detected in the HSE oscillator. Cleared by software setting the CSSC bit.
0: No HSE clock security interrupt
1: HSE clock security interrupt

Bit 9 **MSIPLLHSUF**: MSI PLL mode with HSE unlock interrupt flag

Set by hardware when the PLL mode of MSI using HSE input is unlocked due to HSE failure and MSIPLLHSUIE is set. This occurs when MSI PLL mode using HSE is ready and HSE clock is stopped. In this case, the MSI automatically exits the PLL mode, and MSIPLL0EN/MSIPLL1EN must be cleared by software.

Cleared by software setting the MSIPLLHSUC bit.

0: No MSI PLL mode with HSE unlock interrupt

1: MSI PLL mode with HSE unlock interrupt

Bit 8 **MSIPLLUF**: MSI PLL mode with LSE unlock interrupt flag

Set by hardware when the PLL mode of MSI using LSE input is unlocked due to LSE failure and MSIPLLUIE is set. This occurs when MSI PLL mode using LSE is ready and LSE clock is stopped. In this case, the MSI automatically exits the PLL mode and MSIPLL0EN/MSIPLL1EN must be cleared by software.

Cleared by software setting the MSIPLLUC bit.

0: No MSI PLL mode with LSE unlock interrupt

1: MSI PLL mode with LSE unlock interrupt

Bit 7 **MSIPLL0RDYF**: MSIRC0 PLL mode ready interrupt flag

Set by hardware when the MSIRC0 clock in PLL mode becomes stable and MSIPLL0RDYIE is set. Cleared by software setting the MSIPLL0RDYC bit.

0: No MSIRC0 PLL mode ready interrupt

1: MSIRC0 PLL mode ready interrupt

Bit 6 **MSIPLL1RDYF**: MSIRC1 PLL mode ready interrupt enable

Set by hardware when the MSIRC1 clock in PLL mode becomes stable and MSIPLL1RDYIE is set. Cleared by software setting the MSIPLL1RDYC bit.

0: No MSIRC1 PLL mode ready interrupt

1: MSIRC1 PLL mode ready interrupt

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag

Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set. Cleared by software setting the HSI48RDYC bit.

0: No HSI48 ready interrupt

1: HSI48 ready interrupt

Bit 4 **HSERDYF**: HSE ready interrupt flag

Set by hardware when the HSE clock becomes stable and HSERDYIE is set. Cleared by software setting the HSERDYC bit.

0: No HSE ready interrupt

1: HSE ready interrupt

Bit 3 **HSIRDYF**: HSI16 ready interrupt flag

Set by hardware when the HSI16 clock becomes stable and HSIRDYIE is set in a response to setting the HSION (see RCC_CR). When HSION is not set but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated. Cleared by software setting the HSIRDYC bit.

0: No HSI16 ready interrupt

1: HSI16 ready interrupt

Bit 2 **MSISRDYF**: MSIS ready interrupt flag

Set by hardware when the MSIS clock becomes stable and MSISRDYIE is set. Cleared by software setting the MSISRDYC bit.

0: No MSIS ready interrupt

1: MSIS ready interrupt

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYIE is set. Cleared by software setting the LSERDYC bit.
0: No LSE ready interrupt
1: LSE ready interrupt

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set. Cleared by software setting the LSIRDYC bit.
0: No LSI ready interrupt
1: LSI ready interrupt

10.5.12 RCC clock interrupt clear register (RCC_CICR)

Address offset: 0x058

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LSECSSC**: LSE CSS interrupt clear
Writing this bit to 1 clears the LSECSSF flag. Writing 0 has no effect.

Bit 11 **MSIKRDYC**: MSIK oscillator ready interrupt clear
Writing this bit to 1 clears the MSIKRDYF flag. Writing 0 has no effect.

Bit 10 **CSSC**: Clock security system interrupt clear
Writing this bit to 1 clears the CSSF flag. Writing 0 has no effect.

Bit 9 **MSIPLLHSUC**: MSI PLL mode with HSE unlock interrupt clear
Writing this bit to 1 clears the MSIPLLHSUF flag. Writing 0 has no effect.

Bit 8 **MSIPLLUC**: MSI PLL mode with LSE unlock interrupt clear
Writing this bit to 1 clears the MSIPLLLSUF flag. Writing 0 has no effect.

Bit 7 **MSIPLL0RDYC**: MSIRC0 PLL mode ready interrupt clear
Writing this bit to 1 clears the MSIPLLHSUF flag. Writing 0 has no effect.

Bit 6 **MSIPLL1RDYC**: MSIRC1 PLL mode ready interrupt clear
Writing this bit to 1 clears the MSIPLLLSUF flag. Writing 0 has no effect.

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Writing this bit to 1 clears the HSI48RDYF flag. Writing 0 has no effect.

Bit 4 **HSERDYC**: HSE ready interrupt clear
Writing this bit to 1 clears the HSERDYF flag. Writing 0 has no effect.

Bit 3 **HSIRDYC**: HSI16 ready interrupt clear
Writing this bit to 1 clears the HSIRDYF flag. Writing 0 has no effect.

Bit 2 **MSISRDYC**: MSIS ready interrupt clear
Writing this bit to 1 clears the MSISRDYF flag. Writing 0 has no effect.

Bit 1 **LSERDYC**: LSE ready interrupt clear
Writing this bit to 1 clears the LSERDYF flag. Writing 0 has no effect.

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Writing this bit to 1 clears the LSIRDYF flag. Writing 0 has no effect.

10.5.13 RCC AHB1 peripheral reset register 1 (RCC_AHB1RSTR1)

Address offset: 0x060

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **SDMMC1RST**: SDMMC1 reset
0: No effect
1: Reset SDMMC1

Bits 26:22 Reserved, must be kept at reset value.

Bit 21 **CCBRST**: CCB reset
0: No effect
1: Reset CCB
Note: All the peripheral clocks of the CCB subsystem must be disabled before setting this bit.

Bit 20 **SAESRST**: SAES hardware accelerator reset
0: No effect
1: Reset SAES
Note: All the peripheral clocks of the CCB subsystem must be disabled before setting this bit.

Bit 19 **PKARST**: PKA reset
0: No effect
1: Reset PKA
Note: All the peripheral clocks of the CCB subsystem must be disabled before setting this bit.

Bit 18 **RNGRST**: Random number generator reset
0: No effect
1: Reset RNG
Note: All the peripheral clocks of the CCB subsystem must be disabled before setting this bit.

Bit 17 **HASHRST**: HASH reset
0: No effect
1: Reset HASH
Note: All the peripheral clocks of the CCB subsystem must be disabled before setting this bit.

Bit 16 **AESRST**: AES hardware accelerator reset
0: No effect
1: Reset AES
Note: All the peripheral clocks of the CCB subsystem must be disabled before setting this bit.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **DAC1RST**: DAC1 reset
0: No effect
1: Reset DAC1

Bit 10 **ADC12RST**: ADC12 reset
0: No effect
1: Reset ADC12

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:6 **GPIOiRST**: I/O port i reset (i = H to G)
0: No effect
1: Reset I/O port i

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **GPIOiRST**: I/O port i reset (i = E to A)
0: No effect
1: Reset I/O port i

10.5.15 RCC AHB2 peripheral reset register 2 (RCC_AHB2RSTR2)

Address offset: 0x068

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

0: TIMj clock disabled
1: TIMj clock enabled

10.5.25 RCC APB1 peripheral clock enable register 2 (RCC_APB1ENR2)

Address offset: 0x0A0

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

Note: When the peripheral clock is not active, the peripheral register read or write access is not supported.

Bit 11 **LPTIM1SLPEN**: LPTIM1clock enable during Sleep mode
0: LPTIM1 clock disabled during Sleep mode
1: LPTIM1 clock enabled during Sleep mode

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3SLPEN**: I2C3 clock enable during Sleep mode
0: I2C3 clock disabled by the clock gating during Sleep mode
1: I2C3 clock enabled by the clock gating during Sleep mode

Bit 6 **LPUART1SLPEN**: LPUART1 clock enable during Sleep mode
0: LPUART1 clock disabled by the clock gating during Sleep mode
1: LPUART1 clock enabled by the clock gating during Sleep m

Bits 5:2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGSLPEN**: SYSCFG clock enable during Sleep mode
0: SYSCFG clock disabled by the clock gating during Sleep mode
1: SYSCFG clock enabled by the clock gating during Sleep mode

Bit 0 Reserved, must be kept at reset value.

10.5.36 RCC AHB1 peripheral clock enable in Stop mode register (RCC_AHB1STPENR1)

Address offset: 0x0D8

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word, and byte access

This register only configures the clock gating, not the clock source itself. When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to *Peripherals clock gating and autonomous mode*).

	rw		rw		rw		rw		rw		rw		rw		rw

Bits 31:29 **TIMICSEL[2:0]**: Clock sources for TIM16,TIM17, and LPTIM2 internal input capture

When the TIMICSEL[2] bit is set, TIM16, TIM17, and LPTIM2 internal input capture can be connected either to HSI/256, MSI/4, or MSI/1024. Depending on TIMICSEL[1:0] value, MSI is either MSIK or MSIS.

When TIMICSEL[2] is cleared, the HSI, MSIK, and MSIS clock sources cannot be selected as TIM16, TIM17, or LPTIM2 internal input capture.

000-011: HSI, MSIK and MSIS dividers disabled

100: HSI/256, MSIS/1024 and MSIS/4 are generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture.

101: HSI/256, MSIS/1024 and MSIK/4 are generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture.

110: HSI/256, MSIK/1024 and MSIS/4 are generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture.

111: HSI/256, MSIK/1024 and MSIK/4 are generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture.

Note: The clock division must be disabled (TIMICSEL[2:0] = 0xx) before selecting or changing a clock source division.

Bit 28 **USB1SEL**: USB1 kernel clock prescaler selection

This bit is used to configure the division factor of the USB1 kernel clock source selected with ICLKSEL.

0: usbsdmmc_iclk selected

1: usbsdmmc_iclk/2 selected

Bits 27:26 **ICLKSEL[1:0]**: Intermediate clock source selection

These bits are used to select the clock source for USB and SDMMC (usbsdmmc_iclk).

00: HSI48 selected

01: MSIK selected

10: HSE selected

11: SYSCLK selected

Bit 25 Reserved, must be kept at reset value.

Bit 24 **FDCAN1SEL**: FDCAN1 kernel clock source selection

0: SYSCLK selected

1: MSIK selected

Bits 23:22 **SYSTICKSEL[1:0]**: SysTick clock source selection
00: HCLK/8 selected
01: LSI selected
10: LSE selected
11: reserved
Note: When LSE or LSI is selected, the AHB frequency must be at least four times higher than the LSI or LSE frequency. In addition, a jitter up to one HCLK cycle is introduced, due to the LSE or LSI sampling with HCLK in the SysTick circuitry.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI1SEL**: SPI1 kernel clock source selection
0: PCLK2 selected
1: MSIK selected
Note: The SPI1 is functional in Stop 0 or Stop 1 mode only when the kernel clock is MSIK.

Bits 19:18 **LPTIM2SEL[1:0]**: Low-power timer 2 kernel clock source selection
00: PCLK1 selected
01: LSI selected
10: HSI16 selected
11: LSE selected
Note: The LPTIM2 is functional in Stop 0 or Stop 1 mode only when the kernel clock is LSI, LSE, or HSI16 if HSIKERON = 1.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **SPI2SEL**: SPI2 kernel clock source selection
0: PCLK1 selected
1: MSIK selected
Note: The SPI2 is functional in Stop 0 or Stop 1 mode only when the kernel clock is MSIK.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **I3C2SEL**: I3C2 kernel clock source selection
0: PCLK2 selected
1: MSIK selected
Note: The I3C2 is functional in Stop 0 or Stop 1 mode only when the kernel clock is MSIK.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **I2C2SEL**: I2C2 kernel clock source selection
0: PCLK1 selected
1: MSIK selected
Note: The I2C2 is functional in Stop 0 or Stop 1 mode only when the kernel clock is MSIK.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **I2C1SEL**: I2C1 kernel clock source selection
0: PCLK1 selected
1: MSIK selected
Note: The I2C1 is functional in Stop 0 or Stop 1 mode only when the kernel clock is MSIK.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **I3C1SEL**: I3C1 kernel clock source selection
0: PCLK1 selected
1: MSIK selected
Note: The I3C1 is functional in Stop 0 or Stop 1 mode only when the kernel clock is MSIK.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **UART5SEL**: UART5 kernel clock source selection
0: PCLK1 selected
1: HSI16 selected
Note: The UART5 is functional in Stop 0 or Stop 1 mode only when the kernel clock is HSI16.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **UART4SEL**: UART4 kernel clock source selection
0: PCLK1 selected
1: HSI16 selected
Note: UART4 is functional in Stop 0 or Stop 1 mode only when the kernel clock is HSI16.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **USART3SEL**: USART3 kernel clock source selection
0: PCLK1 selected
1: HSI16 selected
Note: USART3 is functional in Stop 0 or Stop 1 mode only when the kernel clock is HSI16.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **USART1SEL**: USART1 kernel clock source selection
0: PCLK2 selected
1: HSI16 selected
Note: USART1 is functional in Stop 0 or Stop 1 mode only when the kernel clock is HSI16.

10.5.43 RCC peripheral independent clock configuration register 2 (RCC_CCIPR2)

Address offset: 0x104

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

10: HSI16 selected
11: LSE selected
Note: LPTIM3 and LPTIM4 are functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIKERON = 1, or MSIK with MSIKERON = 1.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **I2C3SEL**: I2C3 kernel clock source selection
0: PCLK3 selected
1: MSIK selected
Note: The I2C3 is functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is MSIK.

Bits 5:2 Reserved, must be kept at reset value.

Bits 1:0 **LPUART1SEL[1:0]**: LPUART1 kernel clock source selection
00: PCLK3 selected
01: HSI16 selected
10: LSE selected
11: MSIK selected
Note: The LPUART1 is functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is HSI16, LSE, or MSIK.

10.5.45 RCC backup domain control register (RCC_BDCR)

Address offset: 0x110

Reset value: 0xUUUU UUUU

Backup domain reset value: 0x0000 X000

Reset by backup domain reset, except LSCOSEL, LSCOEN, and BDRST that are reset only by backup domain power-on reset. LSESYSEN and LSESYSRDY are reset by power-on reset.

This register bits are outside of the core domain. As a result, after reset, these bits are write-protected, and DBP in PWR_BDCR must be set before these can be modified (see *Section 10.1: RCC introduction*). These bits (except LSESYSEN, LSESYSRDY, LSCOSEL, LSCOEN, and BDRST) are only reset after a backup domain reset (see *Backup domain reset*). Any internal or external reset does not have any effect on these bits.

Access: 0 ≤ wait state ≤ 3; word, half-word, and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	LSCOSEL	LSCOEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BDRST

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	LSEGFON	LSESYSRDY	Res.	RTCSEL[1:0]		LSESYSEN	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **LSCOSEL**: Low-speed clock output selection
0: LSI selected
1: LSE selected

Bit 24 **LSCOEN**: Low-speed clock output (LSCO) enable
0: LSCO disabled
1: LSCO enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset
0: No effect
1: Reset the entire backup domain

Bit 15 **RTCEN**: RTC and TAMP clock enable
0: RTC and TAMP clock disabled
1: RTC and TAMP clock enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LSEGFON**: LSE clock glitch filter enable
This bit can be written only when the LSE is disabled (LSEON = 0 and LSERDY = 0).
0: LSE glitch filter disabled
1: LSE glitch filter enabled

Bit 11 **LSESYSRDY**: LSE system clock (LSESYS) ready

Set and cleared by hardware to indicate when the LSE system clock is stable.When the LSESYSEN bit is set, the LSESYSRDY flag is set after two LSE clock cycles.

The LSE clock must be already enabled and stable (LSEON and LSERDY are set).

When the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.

0: LSESYS clock not ready

1: LSESYS clock ready

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: RTC and TAMP clock source selection

Once the RTC and TAMP clock source has been selected, it cannot be changed anymore unless the backup domain is reset, or unless a failure is detected on LSE (LSECSSD is set). The BDRST bit can be used to reset them.

00: No clock selected

01: LSE selected

10: LSI selected

11: HSE/32 selected

Bit 7 **LSESYSEN**: LSE system clock (LSESYS) enable

Set by software to enable always the LSE system clock generated by RCC, which can be used by any peripheral when its source clock is the LSE, or at system level if one of LSCO, MCO, or MSI PLL mode is needed.

0: LSE can be used only for RTC, TAMP, and CSS on LSE.

1: LSE can be used by any other peripheral or function.

Bit 6 **LSECSSD**: CSS on LSE failure detection

Set by hardware to indicate when a failure is detected by the CCS on the external 32 kHz oscillator (LSE). This flag is cleared when LSECSSON = 0.

0: No failure detected on LSE

1: Failure detected on LSE

Bit 5 **LSECSSON**: CSS on LSE enable

This bit must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected.

Clearing LSECSSON also clears the LSECSSD bit.

0: CSS on LSE OFF

1: CSS on LSE ON

Bits 4:3 **LSEDRV[1:0]:** LSE oscillator drive capability

This bitfield can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).

00: 'Xtal mode' lower driving capability

01: 'Xtal mode' medium-low driving capability

10: 'Xtal mode' medium-high driving capability

11: 'Xtal mode' higher driving capability

Note: The oscillator is in 'Xtal mode' when it is not in bypass mode.

Bit 2 **LSEBYP**: LSE oscillator bypass

This bit can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).

0: LSE oscillator not bypassed

1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.

0: LSE oscillator not ready

1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enable

0: LSE oscillator OFF

1: LSE oscillator ON

10.5.46 RCC control/status register (RCC_CSR)

Address offset: 0x114

Reset value: 0x0C00 5500

Reset by system reset, except reset flags by power reset only.

Access: 0 ≤ wait state ≤ 3; word, half-word, and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	BORRSTF	PINRSTF	OBLRSTF	Res.	RMVF	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MSISDIVS[1:0]		Res.	Res.	MSIKDIVS[1:0]		Res.	Res.	Res.	Res.	Res.	LSIPREDIV	LSIRDY	LSION
		rw	rw			rw	rw						rw	rw	rw

Bit 31 **LPWRRSTF**: Low-power reset flag

Set by hardware when a reset occurs due to Stop, Standby, or Shutdown mode entry, whereas the corresponding NRST_STOP, NRST_STBY, or NRST_SHDW option bit is cleared. Cleared by writing to the RMVF bit.

0: No illegal low-power mode reset occurred.

1: Illegal low-power mode reset occurred.

Bit 30 **WWDGRSTF**: Window watchdog reset flag

Set by hardware when a window watchdog reset occurs. Cleared by writing to the RMVF bit.

0: No window watchdog reset occurred

1: Window watchdog reset occurred

Bit 29 **IWDGRSTF**: Independent watchdog reset flag

Set by hardware when an independent watchdog reset domain occurs.

Cleared by writing to the RMVF bit.

0: No independent watchdog reset occurred.

1: Independent watchdog reset occurred.

Bit 28 **SFTRSTF**: Software reset flag

Set by hardware when a software reset occurs. Cleared by writing to the RMVF bit.

0: No software reset occurred.

1: Software reset occurred.

Bit 27 **BORRSTF**: BOR flag
Set by hardware when a BOR occurs. Cleared by writing to the RMVF bit.
0: No BOR occurred.
1: BOR occurred.

Bit 26 **PINRSTF**: NRST pin reset flag
Set by hardware when a reset from the NRST pin occurs. Cleared by writing to the RMVF bit.
0: No reset from NRST pin occurred.
1: Reset from NRST pin occurred

Bit 25 **OBLRSTF**: Option-byte loader reset flag
Set by hardware when a reset from the option-byte loading occurs.
Cleared by writing to the RMVF bit.
0: No reset from option-byte loading occurred.
1: Reset from option-byte loading occurred.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag
0: No effect
1: Clear the reset flags.

Bits 22:14 Reserved, must be kept at reset value.

Bits 13:12 **MSISDIVS[1:0]**: MSIS oscillator division after Standby mode
Set by software to choose the MSIS frequency at Standby mode exit, and until MSIRGSEL is set. After a system reset, a power-on reset, or when exiting Shutdown mode, range 5 (12MHz) is always selected. MSISDIVS can be written only when MSIRGSEL = 1.
01: Range 5 around 12 MHz (reset value)
10: Range 6 around 6 MHz
11: Range 7 around 3 MHz
Others: reserved
Note: Changing the MSISDIVS does not change the current MSIS frequency.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **MSIKDIVS[1:0]**: MSIK oscillator division after Standby mode
Set by software to choose the MSIK frequency at Standby mode exit and until MSIRGSEL is set. After a system reset, a power-on reset or when exiting Shutdown mode, range 5 (12MHz) is always selected. MSIKDIVS can be written only when MSIRGSEL = 1.
01: Range 5 around 12 MHz (reset value)
10: Range 6 around 6 MHz
11: Range 7 around 3 MHz
Others: reserved
Note: Changing the MSIKDIVS does not change the current MSIK frequency.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **LSIPREDIV**: Low-speed clock divider configuration
This bit can be written only when the LSI is disabled (LSION = 0 and LSIRDY = 0). If the LSI was previously enabled, it is necessary to wait for LSIRDY = 0 after clearing LSION bit (synchronization time for LSI to be really disabled), before writing LSIPREDIV. LSIPREDIV cannot be changed if the LSI is used by the IWDG, by the RTC, or by the TAMP.
0: LSI not divided
1: LSI divided by 128

Bit 1 **LSIRDY**: LSI oscillator ready

Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles. This bit is set when the LSI is used by IWDG, RTC, or TAMP, even if LSION = 0.

0: LSI oscillator not ready

1: LSI oscillator ready

Bit 0 **LSION**: LSI oscillator enable

0: LSI oscillator OFF

1: LSI oscillator ON

10.5.47 RCC secure configuration register (RCC_SECCFGR)

Address offset: 0x130

Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register can be written only by a secure privileged access if SPRIV = 1, and by a secure privileged or unprivileged access if SPRIV = 0. A nonsecure write access generates an illegal access event and data is not written. This register can be read by secure or nonsecure, privileged or unprivileged access.When the system is not secure (TZEN = 0), this register is read as 0, and the register write is ignored.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **RMVFSEC**: Remove reset flag security

0: Nonsecure

1: Secure

Bit 11 **HSI48SEC**: HSI48 clock configuration and status bit security

0: Nonsecure

1: Secure

Bit 10 **ICLKSEC**: Intermediate clock source selection security

0: Nonsecure

1: Secure

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **BOOSTSEC**: EPOD booster configuration bit security

0: Nonsecure

1: Secure

Bit 6 **PRESCSEC**: AHBx/APBx prescaler configuration bit security
0: Nonsecure
1: Secure

Bit 5 **SYSCLKSEC**: SYSCLK clock selection, STOPWUCK bit, clock output on MCO configuration security
0: Nonsecure
1: Secure

Bit 4 **LSESEC**: LSE clock configuration and status bit security
0: Nonsecure
1: Secure

Bit 3 **LSISEC**: LSI clock configuration and status bit security
0: Nonsecure
1: Secure

Bit 2 **MSISEC**: MSI clock configuration and status bit security
0: Nonsecure
1: Secure

Bit 1 **HSESEC**: HSE clock configuration, status bits, and HSE_CSS security
0: Nonsecure
1: Secure

Bit 0 **HSISEC**: HSI clock configuration and status bit security
0: Nonsecure
1: Secure

10.5.48 RCC privilege configuration register (RCC_PRIVCFGR)

Address offset: 0x134

Reset value: 0x0000 0000

This register can be written only by a privileged access. It can be read by privileged or unprivileged access.

Access: no wait state; word, half-word, and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: RCC nonsecure function privilege configuration
This bit can be written only by privileged access, secure, or nonsecure.
0: Read and write to RCC nonsecure functions can be done by privileged or unprivileged access.
1: Read and write to RCC nonsecure functions can be done by privileged access only.

Bit 0 **SPRIV**: RCC secure function privilege configuration
This bit can be written only by a secure privileged access.
0: Read and write to RCC secure functions can be done by privileged or unprivileged access.
1: Read and write to RCC secure functions can be done by privileged access only.

11 Clock recovery system (CRS)

11.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from alternative synchronization or generated by the user software.

11.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity (see *Section 11.4.2: CRS internal signals*)
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

11.3 CRS implementation

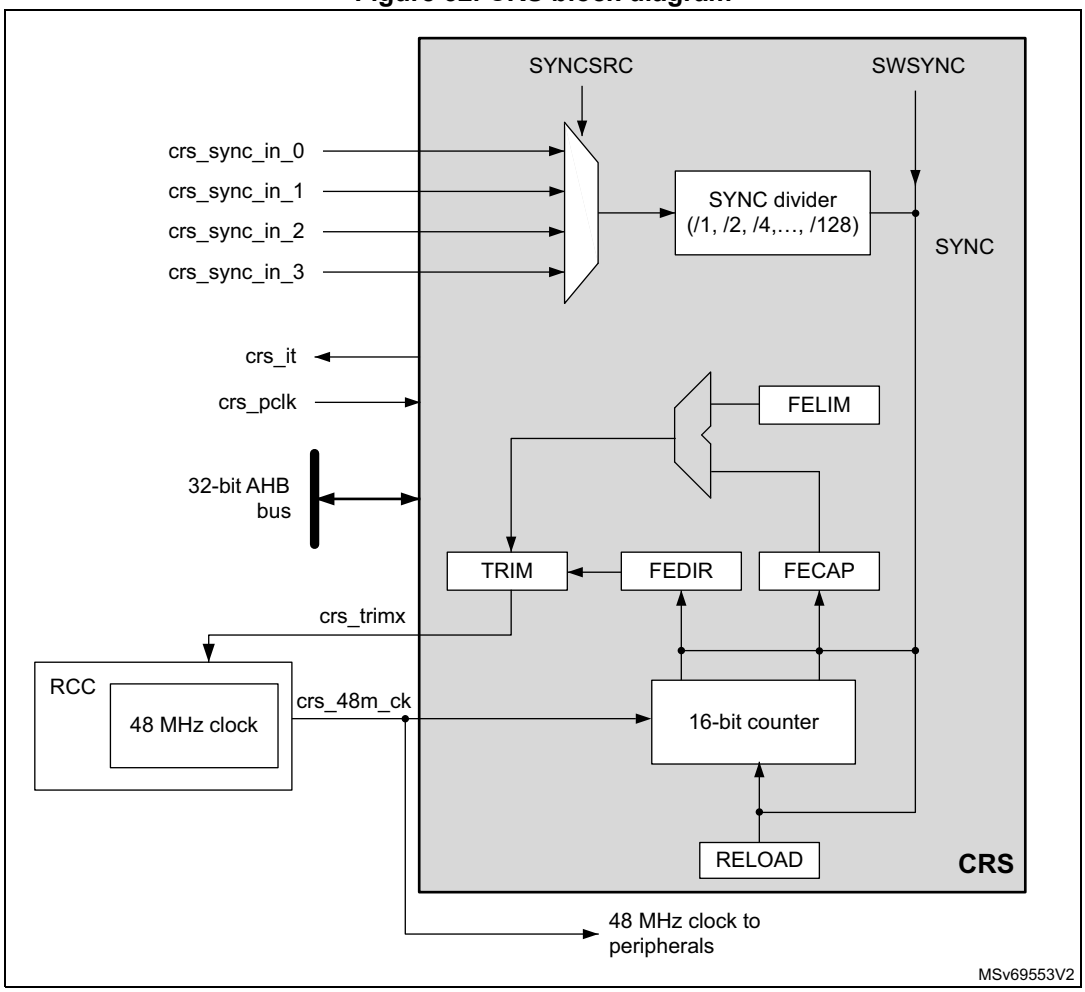

Table 102. CRS features

Feature	CRS
TRIM width	7 bits

11.4 CRS functional description

11.4.1 CRS block diagram

Figure 32. CRS block diagram

11.4.2 CRS internal signals

Below the list of CRS internal signals.

Table 103. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
crs_48m_ck	Digital input	HSI48 48 MHz clock
crs_trim[0:6]	Digital output	HSI48 oscillator smooth trimming value

Table 103. CRS internal input/output signals (continued)

Internal signal name	Signal type	Description
crs_sync_in_0	Digital input	SYNC signal source
crs_sync_in_1		
crs_sync_in_2		
crs_sync_in_3		

Table 104. CRS interconnection

Internal signal name	Source
crs_sync_in_0	CRS_SYNC
crs_sync_in_1	LSE clock
crs_sync_in_2	USB SOF
crs_sync_in_3	Reserved

11.4.3 Synchronization input

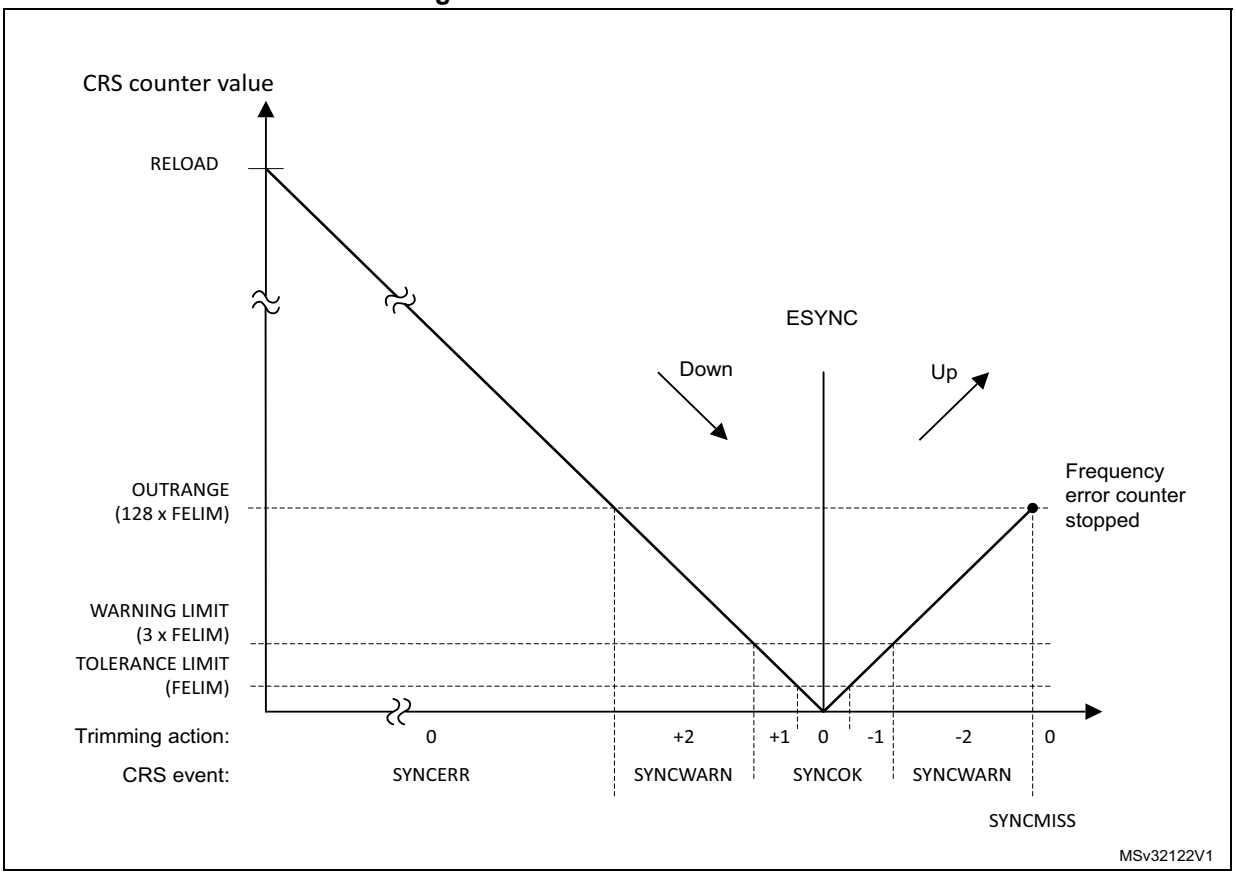
The CRS synchronization source (crs_sync_in_x) can be selected through SYNCSRC[1:0] bitfield of CRS_CFGR register (refer to *Section 11.4.2: CRS internal signals* for the possible sources). For a better robustness of the crs_sync_in_x input, a simple digital filter (2 out of 3 majority votes, sampled by the 48 MHz clock) is implemented to filter out glitches. In addition, the source signal has a configurable polarity (selected through SYNCPOL bit of CRS_CFGR). The signal can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to CRS_CFGR register.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

For more information on the CRS synchronization source configuration, refer to *CRS configuration register (CRS_CFGR)*.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.



11.4.4 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual

frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 33. CRS counter behavior

11.4.5 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated

  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

11.4.6 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

11.5 CRS in low-power modes

Table 105. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator is restarted.
Standby	The peripheral is powered down and must be reinitialized after exiting Standby mode.

11.6 CRS interrupts

Table 106. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

11.7 CRS registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

11.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 4000 (products supporting 7-bit TRIM width)
Reset value: 0x0000 2000 (other products)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TRIM[6:0]							SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNC IE	ERR IE	SYNC WARNIE	SYNC OKIE
	rw	rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **TRIM[6:0]**: HSI48 oscillator smooth trimming

The default value of the HSI48 oscillator smooth trimming is 64, which corresponds to the middle of the trimming interval.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 11.4.5* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled

1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled

1: SYNC event OK (SYNCOKF) interrupt enabled

11.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection

This bit is set and cleared by software to select the input polarity for the SYNC signal source.
0: SYNC active on rising edge (default)
1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see *Section 11.4.2: CRS internal signals*).
00: crs_sync_in_0 selected as SYNC signal source
01: crs_sync_in_1 selected as SYNC signal source
10: crs_sync_in_2 selected as SYNC signal source
11: crs_sync_in_3 selected as SYNC signal source

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the 48 MHz clock on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.
000: SYNC not divided (default)
001: SYNC divided by 2
010: SYNC divided by 4
011: SYNC divided by 8
100: SYNC divided by 16
101: SYNC divided by 32
110: SYNC divided by 64
111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 11.4.5* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 11.4.4* for more details about counter behavior.

11.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 11.4.5* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target

1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled

1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

11.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag

Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag

Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag

Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag

Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

11.7.5 CRS register map

Table 107. CRS register map and reset values

Refer to *Section 2.3* for the register boundary addresses.

12 General-purpose I/Os (GPIO)

12.1 Introduction

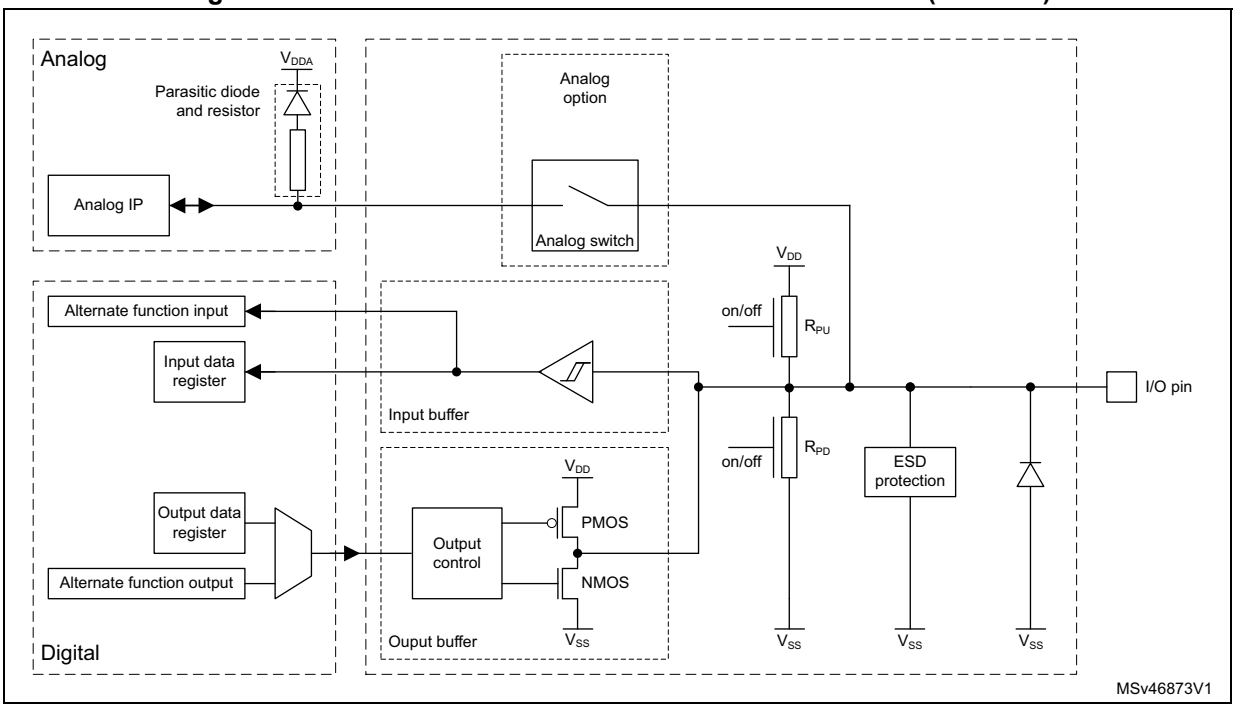
Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16-bit reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL), a secure configuration register (GPIOx_SECCFGR) and a high-speed low-voltage register (GPIOx_HSLVR).

12.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Configurable state of each I/O in Standby mode: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone security support

12.3 GPIO functional description



Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words or bytes. GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). *Table 108* gives the possible port bit configurations.

Figure 34. Structure of three-volt or five-volt tolerant GPIO (TT or FT)

Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

Table 108. Port bit configuration(1)

MODE(i)[1:0]	OTYPE(i)	OSPEED(i)[1:0]	PUPD(i)[1:0]		I/O configuration	
01	0	SPEED[1:0]	0	0	GP output	PP
	0		0	1	GP output	PP + PU
	0		1	0	GP output	PP + PD
	0		1	1	Reserved	
	1		0	0	GP output	OD
	1		0	1	GP output	OD + PU
	1		1	0	GP output	OD + PD
	1		1	1	Reserved (GP output OD)	

Table 108. Port bit configuration[1] (continued)

MODE(i)[1:0]	OTYPE(i)	OSPEED(i)[1:0]		PUPD(i)[1:0]		I/O configuration	
10	0	SPEED[1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0	Input/output	Analog, PD
	x	x	x	1	1	Reserved	

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

12.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see *Section 12.3.15: Using BOOT0 pin as GPIO*).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.

12.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15):

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in GPIOx_MODER.
- **Alternate function**:
  - Connect the I/O to the desired AFx in one of GPIOx_AFRL or GPIOx_AFRH.
  - Select the type, pull-up/pull-down and output speed via GPIOx_OTYPER, GPIOx_PUPDR, and GPIOx_OSPEEDR respectively.
  - Configure the desired I/O as an alternate function in GPIOx_MODER.
  - The Cortex-M33 output EVENTOUT signal can be output as alternate function on several I/Os. An event can be signaled through the configured pin after executing SEV instruction.
  - The Cortex-M33 output EVENTOUT signal can be output as alternate function on several I/O pins. An event can be signaled through the configured pin after executing SEV instruction.
- **Additional functions**:
  - For the ADC, DAC, OPAMP, and COMP, configure the desired I/O in analog mode in GPIOx_MODER, and configure the required function in the ADC, DAC, OPAMP, and COMP registers.
  - For the additional functions like RTC, WKUPx, USB, and oscillators, configure the required function in the related RTC, PWR, USB, and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

12.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os.

- GPIOx_MODER is used to select the I/O mode (input, output, AF, analog).
- GPIOx_OTYPER and GPIOx_OSPEEDR are used to select the output type (push-pull or open-drain) and speed.
- GPIOx_PUPDR is used to select the pull-up/pull-down whatever the I/O direction.

12.3.4 I/O port state in low-power modes

In Standby and Shutdown modes, the GPIO peripheral is not active, and its configuration is forced externally by the PWR control.

Before entering a deep low-power mode, fix the GPIO pin states, using the PWR_PUCRx and PWR_PDCRx registers. This prevents disturbing external components and buses, and optimizes the power consumption during deep low-power modes.

Exiting stop mode causes the power supply to be reset, the PWR_PUCRx and PWR_PDCRx registers to be reset, and the GPIO to be set to floating mode until reset by the application.

12.3.5 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

12.3.6 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

Two control bits in GPIOx_BSRR, BS[i] and BR[i], correspond to each bit in GPIOx_ODR. When written to 1, BS[i] sets the corresponding ODR[i] bit. When written to 1, BR[i] resets the ODR[i] corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using GPIOx_BSRR to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. GPIOx_BSRR provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

12.3.7 GPIO locking mechanism

GPIO control registers can be frozen by applying a specific write sequence to GPIOx_LCKR. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH and GPIOx_HSLVR.

To write GPIOx_LCKR , a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH, and GPIOx_HSLVR).

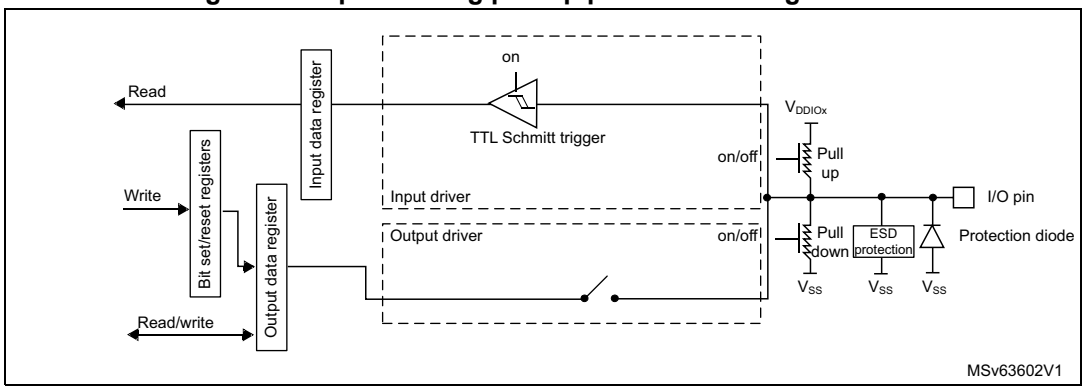
The LOCK sequence can only be performed using a word (32-bit long) access to GPIOx_LCKR due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

12.3.8 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.



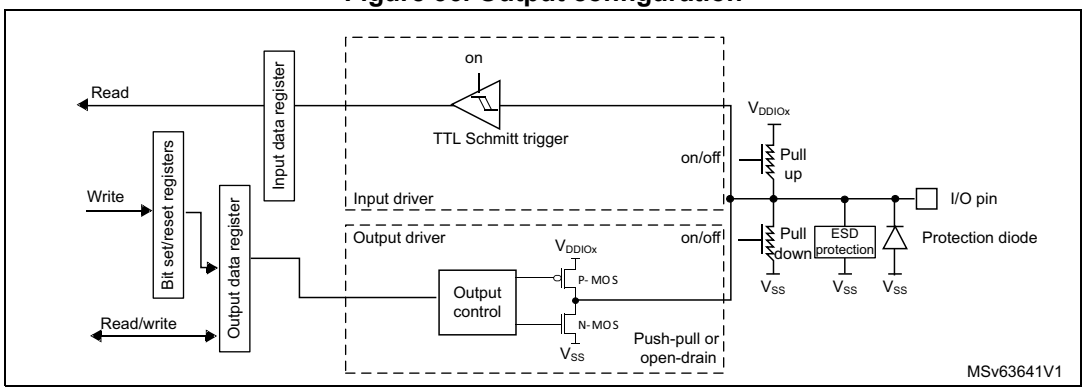
12.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

Figure 35. Input floating/pull-up/pull-down configurations



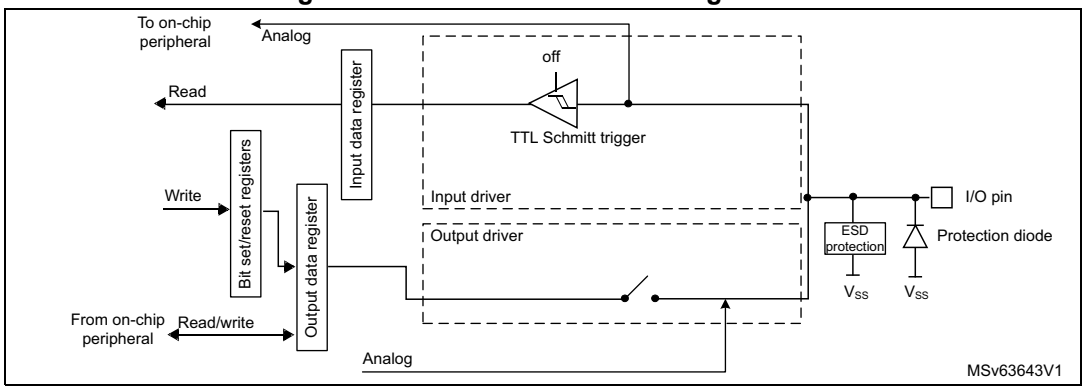
12.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 36. Output configuration



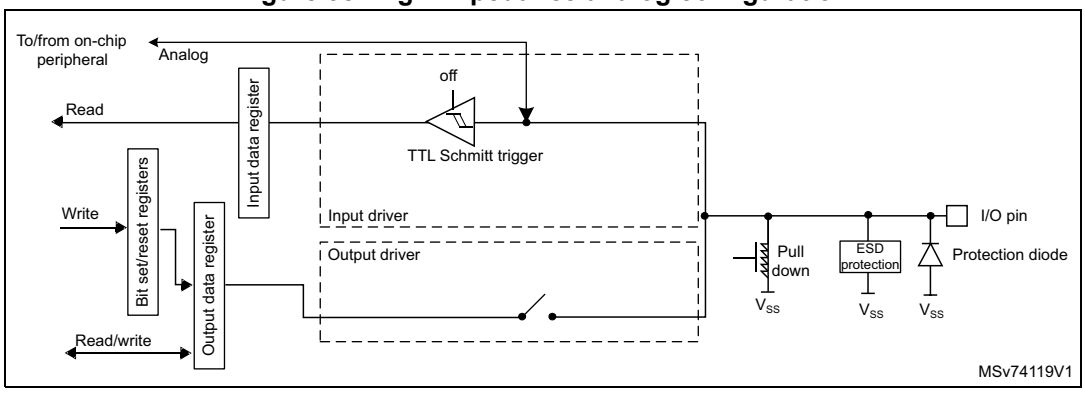
12.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

Figure 37. Alternate function configuration



12.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up is disabled by hardware. The weak pull-down is configurable.
- Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

Figure 38. High-impedance analog configuration

12.3.13 Using HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

12.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 43.3: RTC functional description*.

12.3.15 Using BOOT0 pin as GPIO

PH3 may be used as boot pin (BOOT0) or as a GPIO. Depending on the NSWBOOT0 bit in the user option byte, PH3 switches from the input mode to the analog input mode:

- After the option byte loading phase if NSWBOOT0 = 1.
- After reset if NSWBOOT0 = 0.

Note: On some packages, PH3 is not available and PB7 is used as the BOOT0 pin instead. Refer to the device datasheet for more information.

12.3.16 TrustZone security

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR. When the TrustZone is enabled (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through GPIOx_SECCFGR. This register can be written only by a secure access, a nonsecure write access is ignored. Both secure and nonsecure reads return the register data, that is the security configuration of individual I/O pins.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a nonsecure access. In case of nonsecure access, these bits are RAZ/WI. The GPIO clock and reset control bits in the RCC are automatically configured as secure as soon as at least one I/O in the GPIO is secure.

The I/Os with peripherals functions are also conditioned by the peripheral security configuration (see *Section 5: Global TrustZone controller (GTZC)* for more details):

- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a nonsecure I/O pin. If this is not respected, the input data to the secure peripheral is forced to 0 (I/O input pin value is ignored) and the output pin value is forced to 0, thus avoiding any secure information leak through nonsecure I/Os.
- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a nonsecure peripheral. If this is not respected, the switch remains open. This prevent the redirection of secure data to a nonsecure peripheral or I/O through analog path. Refer to *Table 9: Nonsecure peripherals not connectable to secure I/Os* for more details.
- Some of the paths between I/Os “additional functions” and peripherals are not blocked if the I/O is secure and the peripheral is nonsecure. Therefore it is recommended to configure those peripherals as secure even when not used by the application. Refer to *Table 10: Nonsecure peripherals connectable to secure I/Os* for the list of concerned peripherals. When the path has a security control, it follows the same rule as I/O selection through alternate functions.

Refer to the device pins definition table in datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

For the impacted registers, *Table 109* gives a summary of the secured bits following the individual security configuration bits in the GPIOx_SECCFGR register. When a secure configuration bit is set:

- Secured bits: read and write operations are only allowed by a secure access. Nonsecure read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Nonsecure bits: no restriction. Read and write operations are allowed by both secure and nonsecure accesses.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR), all registers bits are nonsecure. The GPIOx_SECCFGR register is RAZ/WI.

Table 109. GPIO secured bits

Secure configuration bit	Secured bit	Register name	Nonsecure access on secure bits
SECy = 1 in GPIOx_SECCFGR	MODEy[1:0]	GPIOx_MODER	RAZ/WI
	OTy	GPIOx_OTYPER	
	OSPEEDy[1:0]	GPIOx_OSPEEDR	
	PUPDy[1:0]	GPIOx_PUPDR	
	IDy	GPIOx_IDR	
	ODy	GPIOx_ODR	
	BSy and BRy	GPIOx_BSRR	
	LCKy	GPIOx_LCKR	
	BRy	GPIOx_BRR	
	AFSELy[3:0]	GPIOx_AFRH	
		GPIOx_AFRL	
	HSLVy	GPIOx_HSLVR	

12.3.17 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

12.3.18 High-speed low-voltage mode (HSLV)

Some I/Os have the capability to increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1).

Caution: The I/O HSLV configuration bit must not be set if the I/O supply (V_{DD} or V_{DDIO2}) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device. The I/O HSLV bit can be set only when the corresponding option bit is activated (IO_VDD_HSLV or IO_VDDIO2_HSLV depending on the I/O supply, refer to *Section 7: Embedded flash memory (FLASH)*). There is no hardware protection associated to this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

Caution: Setting this bit when the I/O is configured in Fm+ mode is forbidden. An I/O is in Fm+ mode when it is configured as I2C alternate function, with FMP=1 in I2C_CR1 register. PB6, PB7, PB6, PB9 can also be in Fm+ mode when PB6_FMP, PB7_FMP, PB8_FMP, PB9_FMP, respectively, is set in SYSCFG_CFGR1 register.

12.3.19 I/O compensation cell

The I/O commutation slew rate (t_{fall}/t_{rise}) can be adapted by software depending on Process, Voltage and Temperatures conditions, in order to reduce the I/O noise on power supply. Refer to *Section 13: System configuration controller (SYSCFG)* for more details.

12.4 GPIO in low-power modes

Table 110. Effect of low-power modes on the GPIO

Mode	Description
Sleep	No effect. GPIO (EXTI) interrupts cause the device to exit Sleep mode.
Stop	No effect. GPIO (EXTI) interrupts cause the device to exit Stop mode.
Standby	The GPIO digital interface is powered down and must be reinitialized after exiting Standby mode. Wake-up pins can be configured to cause the device to exit Standby mode. I/Os are set to analog mode by hardware. Pull-up or pull-down device can individually be enabled through the PWR_PUCRx and PWR_PDCRx registers, respectively, to keep the I/Os at defined levels.
Shutdown	The GPIO digital interface is powered down and must be reinitialized after exiting Shutdown mode. Wake-up pins can be configured to cause the device to exit Shutdown mode. I/Os are set to analog mode by hardware. Pull-up or pull-down device can individually be enabled through the PWR_PUCRx and PWR_PDCRx registers, respectively, to keep the I/Os at defined levels during Shutdown mode. This setting is reset when exiting and the GPIOs become floating until reinitialized by the application.

12.5 GPIO interrupts

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode). Refer to *Section 17: Extended interrupts and event controller (EXTI)*.

12.6 GPIO registers

The peripheral registers can be written in word, half-word, or byte mode.

The number of GPIOx ports varies in STM32U3 series devices. Refer to the product datasheet for availability of a particular port. If not present, consider the associated bits as reserved and keep them at the reset value.

12.6.1 GPIO port mode register (GPIOx_MODER) (x = A:E, G, H)

Address offset:0x00

Reset value: 0xABFF FFFF (for port A)

Reset value: 0xFFFF FEBF (for port B)

Reset value: 0xFFFF FFFF (for ports C to E)

Reset value: 0xFFFF FFF0 (for port G)

Reset value: 0x0000 00CF (for port H)

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODEy[1:0]:** Port x I/O pin y mode configuration (y = 15 to 0)
These bits are written by software to configure the I/O mode.
00: Input mode
01: General purpose output mode
10: Alternate function mode
11: Analog mode (reset state)

Note: This bitfield is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.2 GPIO port output type register (GPIOx_OTYPER) (x = A:E, G, H)

Address offset: 0x04

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OT15	OT14	OT13	OT12	OT11	OT10	OT9	OT8	OT7	OT6	OT5	OT4	OT3	OT2	OT1	OT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x I/O pin y output type configuration (y = 15 to 0)
These bits are written by software to configure the I/O output type.
0: Output push-pull (reset state)
1: Output open-drain

Note: This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A:E, G, H)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for the other ports)

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEED15[1:0]		OSPEED14[1:0]		OSPEED13[1:0]		OSPEED12[1:0]		OSPEED11[1:0]		OSPEED10[1:0]		OSPEED9[1:0]		OSPEED8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x I/O pin y output speed configuration (y = 15 to 0)
These bits are written by software to configure the I/O output speed.
00: Low speed
01: Medium speed
10: High speed
11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications, and the power supply and load conditions for each speed.
This bitfield is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A:E, G, H)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for the other ports)

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPD15[1:0]		PUPD14[1:0]		PUPD13[1:0]		PUPD12[1:0]		PUPD11[1:0]		PUPD10[1:0]		PUPD9[1:0]		PUPD8[1:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x I/O pin y pull-up/pull-down configuration (y = 15 to 0)
These bits are written by software to configure the I/O pull-up or pull-down
00: No pull-up or pull-down
01: Pull-up
10: Pull-down
11: Reserved

Note: This bitfield is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.5 GPIO port input data register (GPIOx_IDR) (x = A:E, G, H)

Address offset: 0x10

Reset value: 0x0000 XXXX

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x I/O pin y input data (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.6 GPIO port output data register (GPIOx_ODR) (x = A:E, G, H)

Address offset: 0x14

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port x I/O pin y output data (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, these bits can be individually set and/or reset by writing to GPIOx_BSRR or GPIOx_BRR.

This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A:E, G, H)

Address offset: 0x18

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x I/O pin y output reset (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x I/O pin y output set (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A:E, G, H)

Address offset: 0x1C

Reset value: 0x0000 0000

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO.

During the write sequence, LCKR[15:0] value must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Each lock bit freezes corresponding configuration bits in configuration and alternate function registers.

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

Note: A specific write sequence is used to write to this GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified by using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

– LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

– LOCK key read

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the lock key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first lock sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x I/O pin y lock (y = 15 to 0)

These bits are read/write but can only be written when LCKK = 0.

0: Port configuration not locked

1: Port configuration locked

Note: This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.9 GPIO alternate function low register (GPIOx_AFRL) (x = A:E, G, H)

Address offset: 0x20

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note: This bitfield is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.10 GPIO alternate function high register (GPIOx_AFRH) (x = A:E, G, H)

Address offset: 0x24

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

Note: This bitfield is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.11 GPIO port bit reset register (GPIOx_BRR) (x = A:E, G, H)

Address offset: 0x28

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy:** Port x I/O pin y output reset (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Reset the corresponding ODy bit

Note: This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.12 GPIO high-speed low-voltage register (GPIOx_HSLVR) (x = A:E, G, H)

Address offset: 0x2C

Reset value: 0x0000 0000

Individual bits of this register are protected against nonsecure access when corresponding SECy = 1 in GPIO_SECCFGR and the system is secure (TZEN = 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSLV15	HSLV14	HSLV13	HSLV12	HSLV11	HSLV10	HSLV9	HSLV8	HSLV7	HSLV6	HSLV5	HSLV4	HSLV3	HSLV2	HSLV1	HSLV0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HSLVy:** Port x I/O pin y high-speed low-voltage configuration (y = 15 to 0)

These bits are written by software to optimize the I/O speed when the I/O supply is low.

Each bit is active only if the corresponding IO_VDD_HSLV/IO_VDDIO2_HSLV user option bit is set. It must be used only if the I/O supply voltage is below 2.7 V.

Setting these bits when the I/O supply (V_{DD} or V_{DDIO2}) is higher than 2.7 V may be destructive. Setting this bit when the I/O is configured in Fm+ mode is forbidden.

0: I/O speed optimization disabled

1: I/O speed optimization enabled

Note: Not all I/Os support the HSLV mode. Refer to the I/O structure in the corresponding datasheet for the list of I/Os supporting this feature. HSLV configuration for the other I/Os must be kept at reset value.

This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

12.6.13 GPIO secure configuration register (GPIOx_SECCFGR) (x = A:E, G, H)

Address offset: 0x30

Reset value: 0x0000 FFFF (for ports A to E)

Reset value: 0x0000 FFFC (for port G)

Reset value: 0x0000 000B (for port H)

When the system is secure (TZEN = 1), this register is used to configure selected I/O pin as secure. It can be written only by a secure access. A nonsecure write access to this register is ignored. Both nonsecure and secure reads return the register data.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECy**: Port x I/O pin y security configuration (y = 15 to 0)
These bits are written by software to enable or disable the I/O port pin security.
0: The I/O pin is nonsecure
1: The I/O pin is secure. Refer to *Table 109: GPIO secured bits* for all corresponding secured bits.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

13 System configuration controller (SYSCFG)

13.1 SYSCFG main features

The STM32U3 series devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Managing robustness feature
- Configuring FPU interrupts
- Enabling/disabling the FMP high-drive mode of some I/Os and voltage booster for I/Os analog switches
- Managing the I/O compensation cell
- Configuring register security access

13.2 SYSCFG functional description

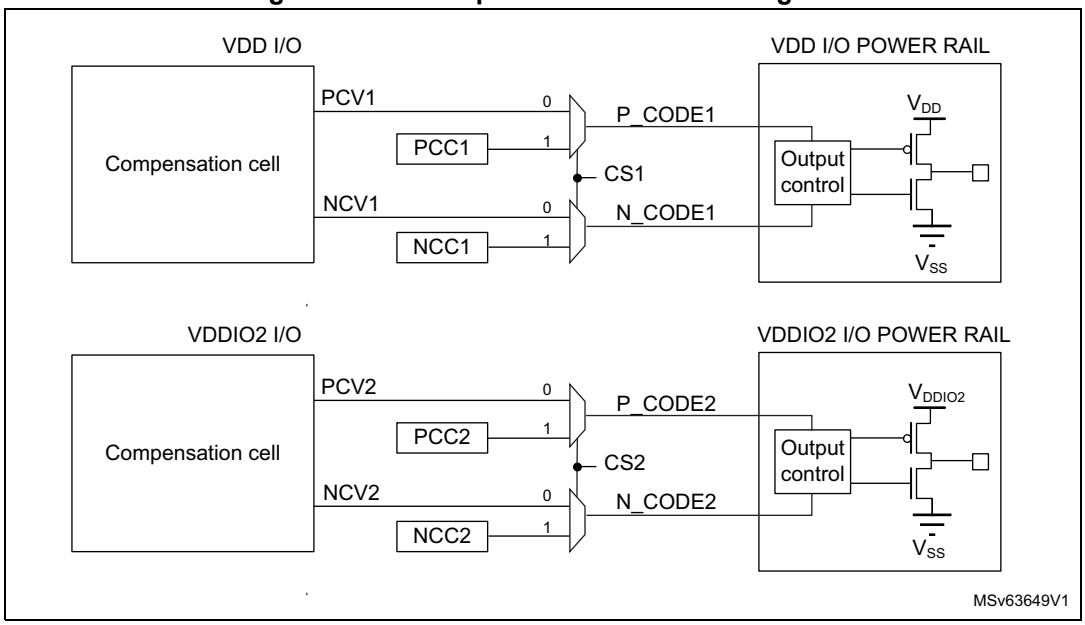
13.2.1 I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the current slew-rate and output impedance in the I/O buffer. Two compensation cells are embedded, one for the I/Os supplied by V_{DD} and one for the I/Os supplied by V_{DDIO2}.

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os. The HSI is used by the compensation cells and must be enabled before enabling the compensation cells in SYSCFG_CCCSR.

When enabled, the compensation cell tracks the PVT, and the 8-bit code PCVx and NCVx (x = 1 for I/Os supplied by V_{DD}, x = 2 for I/Os supplied by V_{DDIO2}) are available in SYSCFG_CCVR once the RDYx is set. If the CSx bit is cleared, the I/Ox receives the code from SYSCFG_CCVR, resulting from the compensation cell.

To optimize the trimming, the code can be adjusted through SYSCFG_CCCR. Two sets of bits are available:



- PCC1/NCC1 for the V_{DD} power rail
- PCC2/NCC2 for the V_{DDIO2} power rail

They can be selected independently through CS1 and CS2 bits in SYSCFG_CCCSR (see *Figure 39*).

To reduce the power consumption, it is recommended to copy the code from SYSCFG_CCVR to SYSCFG_CCCR. After the result is ready, set the CSx bit and disable the compensation cell.

Note: The compensation cell can be used only when 1.6 V ≤ V_{DDIOx} ≤ 3.6 V.

Figure 39. I/O compensation cell block diagram

13.2.2 SYSCFG TrustZone security and privilege

SYSCFG TrustZone security

When the TrustZone security is activated, the SYSCFG is able to secure registers from being modified by nonsecure accesses.

The TrustZone security is activated by the TZEN option bit in FLASH_OPTR.

A nonsecure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SYSCFG illegal access event is enabled in the GTZC.

Privileged/unprivileged mode

SYSCFG registers can be read and written by privileged and unprivileged accesses except the SYSCFG registers for CPU configuration: SYSCFG_CSLCKR, SYSCFG_FPUIMR, and SYSCFG_CNSLCKR registers, and the FPUSEC bit in SYSCFG_SECCFGR.

An unprivileged access to a privileged register is RAZ/WI.

The table below shows the register security overview.

Table 112. TrustZone security and privilege register accesses

SYSCFG register	Read/write access		Privileged /unprivileged access
TrustZone configuration(1)	TZEN = 1	TZEN = 0	Not applicable
SYSCFG_SECCFGR	Read: no restriction Write: secure access only nonsecure write is WI and generates an illegal access event.	RAZ/WI	Read: no restriction FPUSEC privileged write only Other bits write: no restriction
SYSCFG_CSLCKR	Read/Write: secure access only Nonsecure access is RAZ/WI and generates an illegal access event.	RAZ/WI	Privileged only Unprivileged: RAZ/WI
SYSCFG_FPUIMR	If FPUSEC = 1: Read/Write: secure access only Nonsecure access is RAZ/WI and generates an illegal access event. If FPUSEC = 0: Read/Write: no restriction	No restriction	Privileged only Unprivileged: RAZ/WI
SYSCFG_CNSLCKR	Read/write: no restriction	No restriction	Privileged only Unprivileged: RAZ/WI
SYSCFG_CFGR1	Read/Write: secure access only for secure bits depending on peripheral security bits in GTZC Nonsecure access only for nonsecure bits, otherwise RAZ/WI	No restriction	No restriction
SYSCFG_CFGR2	If CLASSBSEC = 1: Read/Write: secure access only Nonsecure access is RAZ/WI and generates an illegal access event. If CLASSBSEC = 0:Read/Write: no restriction	No restriction	No restriction
SYSCFG_CCCSR SYSCFG_CCVR SYSCFG_CCCR	If SYSCFGSEC = 1: Read/Write: secure access only Nonsecure access is RAZ/WI and generates an illegal access event If SYSCFGSEC = 0: Read/Write: no restriction	No restriction	No restriction
SYSCFG_RSSCMDR	RAZ/WI if register access is not allowed(2)	RAZ/WI	No restriction

1. TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.
2. Refer to register description for register access.

13.2.3 GPIO analog switches supply selection

Two bits from the SYSCFG_CFGR1 register are used to select the power supply of the I/O analog switches (used analog input signal paths): BOOSTEN and ANASWVDD.

They have to be initialized according to the voltage of the V_{DD} and V_{DDA} power supplies. When V_{DDA} voltage is larger than 2.4 V, the I/O analog switches must be powered by V_{DDA}.

When V_{DDA} voltage is lower than 2.4 V and V_{DD} is higher than 2.4 V, the I/O analog switches must be powered by V_{DD}. When both V_{DD} and V_{DDA} voltages are lower than 2.4 V, the I/O analog switches must be powered by the output of the V_{DD} booster. When I/O analog switches are supplied by V_{DDA} or V_{DD} booster, the ASV bit of the PWR_SVMCR register must be set.

Table 113. BOOSTEN and ANASWVDD set/reset

VDD	VDDA	BOOSTEN	ANASWVDD
-	> 2.4 V	0	0
> 2.4 V	< 2.4 V		1
< 2.4 V		1	0

13.3 SYSCFG registers

13.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register provides write access security and can be written only when the access is secure. This register can be globally write-protected. Each bit can be individually write-protected. A nonsecure write access is WI and generates an illegal access event. There are no read restrictions.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access, except for FPUSEC that can be written only with privileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPUSEC	Res.	CLASSBSEC	SYSCFGSEC
												rw		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **FPUSEC**: FPU security
0: SYSCFG_FPUIMR can be read and written by secure and nonsecure access.
1: SYSCFG_FPUIMR can be read and written by secure access only.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CLASSBSEC**: Class B security
0: SYSCFG_CFGR2 can be read and written by secure and nonsecure access.
1: SYSCFG_CFGR2 can be read and written by secure access only.

Bit 0 **SYSCFGSEC**: Security of SYSCFG clock control, memory erase status, and compensation cell registers

0: SYSCFG configuration clock in RCC registers and SYSCFG_CCCSR, SYSCFG_CCVR, and SYSCFG_CCCR can be read and written by secure and nonsecure access.

1: SYSCFG configuration clock in RCC registers and SYSCFG_CCCSR, SYSCFG_CCVR, and SYSCFG_CCCR can be read and written by secure access only.

13.3.2 SYSCFG configuration register 1 (SYSCFG_CFGR1)

Address offset: 0x04

Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register can be a mix of secure and nonsecure bits depending on the ADC security configuration bit in GTZC peripheral and GPIO security bits. A nonsecure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PB9_FMP	PB8_FMP	PB7_FMP	PB6_FMP

						rw	rw	rw	rw	rw					

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **PBi_FMP**: Fast-mode Plus driving capability activation on PBi (i = 9 to 6)

This bit can be read and written only with secure access if PB9 is secure in GPIOB. This bit enables the Fm+ driving mode for PBi when PBi is not used by the I2C peripheral. This can be used to drive a LED for instance.

0: PBi pin operates in standard mode.

1: Fm+ mode is enabled on PBi pin and the speed control is bypassed.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **ANASWVDD**: GPIO analog switch control voltage selection

This bit can be read and written only with secure access if ADC1 or ADC2 is secure in GTZC.

0: If booster if OFF: I/O analog switches are supplied by V_{DDA} if ASV = 1 in PWR_SVMCR, or by V_{DD} if ASV = 0.
If booster is ON: I/O analog switches are supplied by booster.

1: I/O analog switches are supplied by V_{DD}.

Note: Refer to Table 113: BOOSTEN and ANASWVDD set/reset

Bit 8 **BOOSTEN**: I/O analog switch voltage booster enable

This bit is only effective when ASV = 1 in PWR_SVMR, and ANASWVDD = 0.

This bit can be read and written only with secure access if ADC1 or ADC2 is secure in GTZC.

0: I/O analog switches are supplied by V_{DDA} voltage.

1: I/O analog switches are supplied by a dedicated voltage booster (supplied by V_{DD}).

Note: Refer to Table 113: BOOSTEN and ANASWVDD set/reset

Bits 7:6 **IR_MOD[1:0]**: IR modulation envelope signal selection
This bitfield can be read and written only with secure access if TIM17 is secure in GTZC.
It selects the signal for IR modulation envelope.
00: TIM16
01: USART1
10: UART4
11: Reserved
Note: Refer to Table 113: BOOSTEN and ANASWVDD set/reset.

Bit 5 **IR_POL**: IR output polarity selection
This bit can be read and written only with secure access if TIM17 is secure in GTZC.
0: Output of IRTIM (IR_OUT) is not inverted.
1: Output of IRTIM (IR_OUT) is inverted.
Note: Refer to Table 113: BOOSTEN and ANASWVDD set/reset.

Bits 4:0 Reserved, must be kept at reset value.

13.3.3 SYSCFG FPU interrupt mask register (SYSCFG_FPUIMR)

Address offset: 0x08

Reset value: 0x0000 001F

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the FPUSEC bit in the SYSCFG_SECCFGR register: a nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 0 **FPU_IOIE**: Floating point unit interrupt enable bit - invalid operation
FPU invalid operation interrupt enable bit
0: Interrupt disabled
1: Interrupt enabled

13.3.4 SYSCFG CPU nonsecure lock register (SYSCFG_CNSLCKR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is used to lock the configuration of nonsecure MPU and VTOR_NS registers. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKNSMPU	LOCKNSVTOR
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LOCKNSMPU**: Nonsecure MPU registers lock
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to nonsecure MPU_CTRL_NS, MPU_RNR_NS, and MPU_RBAR_NS registers.
0: Nonsecure MPU register write enabled
1: Nonsecure MPU register write disabled

Bit 0 **LOCKNSVTOR**: VTOR_NS register lock
This bit is set by software and cleared only by a system reset.
0: VTOR_NS register write enabled
1: VTOR_NS register write disabled

13.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLCKR)

Address offset: 0x10

Reset value: 0x0000 0000

This register is used to lock the configuration of PRIS and BFHFNMINS in AIRCR register, SAU, secure MPU, and VTOR_S registers.

When the system is secure (TZEN = 1), this register can be written only when the access is secure. A nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), this register is RAZ/WI. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKSAU	LOCKSMPU	LOCKSVTAIRCR
													rs	rs	rs

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKSAU**: SAU register lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to SAU_CTRL, SAU_RNR, SAU_RBAR, and SAU_RLAR registers.

0: SAU register write enabled

1: SAU register write disabled

Bit 1 **LOCKSMPU**: Secure MPU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to secure MPU_CTRL, MPU_RNR, and MPU_RBAR registers.

0: Secure MPU register writes enabled

1: Secure MPU register writes disabled

Bit 0 **LOCKSVTAIRCR**: VTOR_S register and AIRCR register bits lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to VTOR_S register, PRIS and BFHFNMINS bits in the AIRCR register.

0: VTOR_S register PRIS and BFHFNMINS bits in AIRCR register write enabled

1: VTOR_S register PRIS and BFHFNMINS bits in AIRCR register write disabled

13.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2)

Address offset: 0x14

Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the CLASSBSEC bit in the SYSCFG_SECCFGR register.

When CLASSBSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCL	PVDL	SPL	CLL
												rs	rs	rs	rs

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCL**: ECC lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the FLASH ECC double error signal connection to the TIM1/15/16/17 break input.

0: ECC double error disconnected from TIM1/15/16/17 break input

1: ECC double error connected to TIM1/15/16/17 break input

Bit 2 **PVDL**: PVD lock enable bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/15/16/17 break input, as well as the PVDE and PVDLS[2:0] in the PWR register.

0: PVD interrupt disconnected from TIM1/15/16/17 break input. PVDE and PVDLS[2:0] bits can be programmed by the application.

1: PVD interrupt connected to TIM1/15/16/17 break input. PVDE and PVDLS[2:0] bits are read only.

Bit 1 **SPL**: SRAM2 parity bit

This bit is set by the software and cleared only by a system reset. It can be used to enable and lock the SRAM2 parity error signal connection to TIM1/15/16/17 break inputs.

0: SRAM double error disconnected from TIM1/15/16/17 break inputs

1: SRAM double error connected to TIM1/15/16/17 break inputs

Bit 0 **CLL**: Cortex-M33 LOCKUP (HardFault) output enable

This bit is set by the software and cleared only by a system reset. It can be used to enable and lock the connection of Cortex-M33 LOCKUP (HardFault) output to TIM1/15/16/17 break input.

0: Cortex-M33 LOCKUP output disconnected from TIM1/15/16/17 break inputs

1: Cortex-M33 LOCKUP output connected to TIM1/15/16/17 break inputs

13.3.7 SYSCFG compensation cell control/status register (SYSCFG_CCCSR)

Address offset: 0x1C

Reset value: 0x0000 000A

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in SYSCFG_SECCFGR register. When the SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	RDY2	RDY1	Res.	Res.	Res.	Res.	CS2	EN2	CS1	EN1
						r	r					rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **RDY2:** VDDIO2 I/O compensation cell ready flag

This bit provides the compensation cell status of the I/Os supplied by V_{DDIO2}.

0: VDDIO2 I/O compensation cell not ready

1: VDDIO2 I/O compensation cell ready

*Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (*RDY2*) is not set if the HSI clock is not enabled.*

Bit 8 **RDY1:** VDD I/O compensation cell ready flag

This bit provides the compensation cell status of the I/Os supplied by V_{DD}.

0: VDD I/O compensation cell not ready

1: VDD I/O compensation cell ready

*Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (*RDY1*) is not set if the HSI clock is not enabled.*

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CS2:** VDDIO2 I/O code selection

This bit selects the code to be applied for the compensation cell of the I/Os supplied by V_{DDIO2}.

0: VDDIO2 I/O code from the cell (available in SYSCFG_CCVR)

1: VDDIO2 I/O code from SYSCFG_CCCR

Bit 2 **EN2:** VDDIO2 I/O compensation cell enable

This bit enables the compensation cell of the I/Os supplied by V_{DDIO2}.

0: VDDIO2 I/O compensation cell disabled

1: VDDIO2 I/O compensation cell enabled

Bit 1 **CS1:** VDD I/O code selection

This bit selects the code to be applied for the compensation cell of the I/Os supplied by V_{DD}.

0: VDD I/O code from the cell (available in the SYSCFG_CCVR)

1: VDD I/O code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

Bit 0 **EN1:** VDD I/O compensation cell enable
This bit enables the compensation cell of the I/Os supplied by V_{DD}.
0: VDD I/O compensation cell disabled
1: VDD I/O compensation cell enabled

13.3.8 SYSCFG compensation cell value register (SYSCFG_CCVR)

Address offset: 0x20

Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When the SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PCV2[3:0]:** PMOS compensation value of the I/Os supplied by V_{DDIO2}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS2 bit in SYSCFG_CCCSR is reset.

Bits 11:8 **NCV2[3:0]:** NMOS compensation value of the I/Os supplied by V_{DDIO2}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS2 bit in SYSCFG_CCCSR is reset.

Bits 7:4 **PCV1[3:0]:** PMOS compensation value of the I/Os supplied by V_{DD}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS1 bit in SYSCFG_CCCSR is reset.

Bits 3:0 **NCV1[3:0]:** NMOS compensation value of the I/Os supplied by V_{DD}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS1 bit in SYSCFG_CCCSR is reset.

13.3.9 SYSCFG compensation cell code register (SYSCFG_CCCR)

Address offset: 0x24

Reset value: 0x0000 7878

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PCC2[3:0]:** PMOS compensation code of the I/Os supplied by V_{DDIO2}
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS2 bit is set in SYSCFG_CCCSR.

Bits 11:8 **NCC2[3:0]:** NMOS compensation code of the I/Os supplied by V_{DDIO2}
These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS2 bit is set in SYSCFG_CCCSR.

Bits 7:4 **PCC1[3:0]:** PMOS compensation code of the I/Os supplied by V_{DD}
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS1 bit is set in SYSCFG_CCCSR.

Bits 3:0 **NCC1[3:0]:** NMOS compensation code of the I/Os supplied by V_{DD}
These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS1 bit is set in SYSCFG_CCCSR.

13.3.10 SYSCFG RSS command register (SYSCFG_RSSCMDR)

Address offset: 0x2C

Power-on reset value: 0x0000 0000

System reset value: 0xUUUU UUUU (not affected)

When the system is secure (TZEN = 1), this register can be read and written only when the APB access is secure. Otherwise it is RAZ/WI.

When the system is not secure (TZEN = 0), this register is RAZ/WI. This register can be read and written by privileged and unprivileged access.

14 Peripherals interconnect matrix

14.1 Interconnect matrix introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep, Stop 0, Stop 1, Stop 2, and Stop 3 modes.

14.2 Connection summary

14.3 Interconnection details

14.3.1 Master to slave interconnection for timers

From timer (TIM1/2/3/4/15/16/17) to timer (TIM1/2/3/4/15).

Purpose

Some of the TIMx timers are linked together internally for timer synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop, or clock the counter of another timer configured in slave mode.

A description of the feature is provided in *Section 35.3.32: ADC synchronization*.

The synchronization modes are detailed in:

- *Section 35.3.32: ADC synchronization*
- *Section 36.4.22: Timers and external trigger synchronization*
- *Section 38.4.23: External trigger synchronization (TIM15 only)*

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/17. The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3.

The possible master/slave connections are given in:

- *Table 347: Internal trigger connection*
- *Table 371: TIMx internal trigger connection*
- *Table 393: TIMx internal trigger connection*

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 360: Effect of low-power modes on TIM1*
- *Table 379: Effect of low-power modes on TIM2/TIM3/TIM4*
- *Table 400: Effect of low-power modes on TIM15/TIM16/TIM17*

14.3.2 Triggers to ADCs

From EXTI, timers (TIM1/2/3/4/6/15) and LP timers (LPTIM1/2/3/4) to ADC1/2

Purpose

A conversion, or a sequence of conversions, can be triggered either by software or by an external event (such as timer capture or input pins). For ADC1/2, if the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events can trigger a conversion with the selected polarity.

More details in:

- *Section 22.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*
- EXTEN[1:0] defined in *ADC configuration register (ADC_CFGR1)*

- JEXTEN[1:0] defined in *ADC injected sequence register (ADC_JSQR)*

General-purpose timers (TIM2/3/4), basic timer (TIM6), advanced-control timers (TIM1), and general-purpose timer (TIM15) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/ 2/3/4) can be used to generate the ADC triggering event through the LPTIM channels (TIMx synchronization described in *Section 35.3.32: ADC synchronization*) in addition to the EXTI on channels 11 and 15.

Triggering signals

For ADC1/2, the input triggering signals and the description of the interconnection between ADC1/2, and timers, are given in:

- adc_ext_trgi: *Table 178: ADC1/2 interconnection*
- adc_jext_trgi: *Table 178: ADC1/2 interconnection*
- *Section 22.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*
- *Section 22.4.25: Timing diagram examples (single/continuous modes, hardware/software triggers)*)

Active power mode

This interconnection is active in Run and Sleep modes for all ADCs. The timers are active in Run and Sleep modes only. The effects of low-power modes are given in:

- *Table 360: Effect of low-power modes on TIM1*
- *Table 400: Effect of low-power modes on TIM15/TIM16/TIM17*
- *Table 406: STM32U3 series LPTIM features*
- *Table 422: Effect of low-power modes on the LPTIM*

14.3.3 ADC analog watchdogs as triggers to timers

From ADC1/2 to TIM1/3

Purpose

The internal analog watchdog output signals coming from ADC1/2, are connected to on-chip timers. ADC1/2 can provide trigger event through analog watchdog signals to timers (TIM1/3) in order to reset, start, stop, or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- *Section 35.3.6: External trigger input* for TIM1
- *Table 348: Interconnect to the tim_etr input multiplexer* for the internal ADC1/2 sources connected to TIM1 (tim_etr) input multiplexer
- *Table 372: Interconnect to the tim_etr input multiplexer* for the internal ADC1/2 sources connected to TIM3 (tim_etr) input multiplexer
- *Section 22.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)* for the ADCn/ADC_AWDy_OUT signal output generation

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

Active power mode

ADC1/2 are active in Run and Sleep modes.

14.3.4 Triggers to DAC

From timer (TIM1/2/4/6/7/15), LP timers (LPTIM1/3) and EXTI to DAC (DAC1)

Purpose

General-purpose timers (TIM2/4/15), basic timers (TIM6/7), advanced control timers (TIM1), LP timers (LPTIM1/3) outputs channels (lptim1_ch1 and lptim3_ch1), and EXTI can be used as triggering event to start a DAC conversion.

Triggering signals

The output (from timer) on the TIMx_TRGO signal and from LP timers are directly connected to corresponding DAC inputs.

The selection of input triggers on DAC is provided in:

- *Table 197: DAC interconnection*
- *Section 23.4.8: DAC trigger selection*

Active power mode

This interconnect is active in Run, Sleep, Stop 0, Stop 1, and Stop 2 modes.

14.3.5 Triggers to ADF1

ADF1 can be triggered by EXTI15, tim1_trgo, tim3_trgo, and tim6_trgo.

Purpose

EXTI15, tim1_trgo, tim3_trgo, and tim6_trgo can trigger ADF1.

Triggering signals

ADF trigger inputs connections are detailed in:

- *Table 224: ADF trigger connections*

Active power mode

This interconnection remains active down Stop 0, Stop 1,and Stop 2 modes for ADF1, assuming the trigger source remains active.

14.3.6 Data input to ADF1

ADF1 peripheral can directly use data input from ADC1/2.

Purpose

ADC1/2 data stream can be routed to ADF1 for direct post-processing.

Triggering signals

ADF trigger inputs connections are detailed in:

- *Table 224: ADF trigger connections*

Active power mode

This interconnection is active in Run and Sleep modes.

14.3.7 Clock sources to timers

From HSE, LSE, LSI, MSIK, HSI and MCO to timers (TIM1/2/3/4/15/16/17) and LP timers (LPTIM1/2/3)

Purpose

A timer input or timer counter can receive different clock sources and can be used to calibrate internal oscillator on a reference clock for example.

External clocks (HSE, LSE), internal clocks (LSI, MSI, HSI), and microcontroller output clock (MCO) can be used as input to timers:

- MSIK/HSI are assigned to advanced-control timer TIM1 as external trigger signals inputs (tim_etr3/ tim_etr4). MSIK/HSI can be selected as counter clock provided by an external clock source in mode2: external trigger input (tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 35.3.7: Clock selection* for TIM1
  - *Table 348: Interconnect to the tim_etr input multiplexer* for TIM1
- MSIK, HSI, and LSE are assigned to general purpose timers TIM2/3/4 as external inputs signals. MSIK/HSI/LSE can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 36.4.5: Clock selection* for TIM2/3/4
  - External clock mode2: *Table 348: Interconnect to the tim_etr input multiplexer*, tim_etr3 (MSIK), tim_etr4 (HSI) for TIM2/3/4, tim_etr5 (MSIS) for TIM4 and tim_etr11 (LSE) for TIM2.
- LSE, LSI, MSI, and HSI are assigned to general purpose timers TIM15/16/17 as external inputs signals. LSE/LSI/MSI/HSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1 or tim_ti2 signals). Inputs assignment and clock selection description are detailed in:
  - *Table 38.4.6: Clock selection* for TIM15/16/17. External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
  - *Table 391: Interconnect to the tim_ti1 input multiplexer*, tim_ti1_in1 (LSE-TIM15), tim_ti1_in5(LSE-TIM16/17), tim_ti1_in6 (LSI- TIM16/17), tim_ti1_in7/_8 (MSI-TIM16/17), and tim_ti1_in9 (HSI-TIM16/17)
- Microcontroller output clock (MCO) is connected as external input to general-purpose timers TIM16/17. This allows the calibration of the HSI16/MSI system clocks (with TIM15/16 and LSE) or LSI (with TIM16 and HSE). This is also used to precisely measure LSI (with TIM16 and HSI16) or MSI (with TIM17 and HSI16) oscillator

frequency. When the low-speed external (LSE) oscillator is used, no additional hardware connections are required. This feature is given in:

  – *Section : Internal/external clock measurement with TIM15/TIM16/TIM17*
  – *Table 343: Interconnect to the tim_ti1 input multiplexer* for TIM15/TIM16/TIM17

- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in *Table 416: LPTIM1 input capture 2 connections*.
- HSI/256, MSI/1024, and MSI/4 can be selected as input capture 2 to LPTIM2 as described in*Table 416: LPTIM1 input capture 2 connections*.

Triggering signals

lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration register 2 (LPTIM_CFGR2). For timers, the internal clock signal can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in).

Active power mode

This feature is available under Run and Sleep modes.

14.3.8 Triggers to low-power timers

From comparators (COMP1/2), EXTI, TAMP and RTC alarm to LP timers (LPTIM1/2/3/4)

Purpose

LPTIM1/2/3/4 counters can be started either by software or after the detection of an active edge on one of the eight trigger inputs (see *Section 39.4.7: Trigger multiplexer*).

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection, according to the LPTIM configuration register 2 (LPTIM_CFGR2).

Triggering signals

This trigger feature is described in *Section 39.4.7: Trigger multiplexer* and the following sections. The input selection is described in *Section 39.4.3: LPTIM input and trigger mapping*.

Active power mode

This interconnection remains active down to Stop 2 mode.

14.3.9 Blanking sources to comparators

From timers (TIM1/2/3/4/15/16/17) to comparators (COMP1/2)

Purpose

Advanced-control timers (TIM1) and general-purpose timers (TIM2/3/4/15/16/17) can be used as blanking window input to COMP1/2.

The blanking function is described in *Section 25.3.6: Comparator output-blanking function*.

The blanking sources are given in:

- *Table 212: COMP1 output-blanking PWM assignment*, BLANKSEL[4:0]

- *Table 213: COMP2 output-blanking PWM assignment*, BLANKSEL[4:0]

Triggering signals

Timer output signal TIMx_Ocx are the inputs to blanking source of COMP1/2.

Active power mode

This feature is available under Run and Sleep modes.

14.3.10 RTC wake-up as inputs to timers

From RTC to timers (TIM16/17)

Purpose

RTC wake-up interrupt can be used as input to general-purpose timers (TIM16/17) channel 1.

Triggering signals

RTC wake-up signal is connected to tim_ti1_in4 signal as described in *Table 391: Interconnect to the tim_ti1 input multiplexer* for TIM16/17.

Active power mode

This interconnection is active down to Stop 3 mode. Timers are not active but the count is performed at wake-up.

14.3.11 USB SOF as trigger to timers

From USB SOF to TIM2

Purpose

USB SOF (start-of-frame) can generate a trigger to the general-purpose timer TIM2. The USB connection to TIM2 is described in *Table 372: Interconnect to the tim_etr input multiplexer*.

Triggering signals

The tim_etr13 internal signal is generated by USB SOF.

Active power mode

This interconnection is active in Run and Sleep modes.

14.3.12 Comparators as inputs, trigger or break signals to timers

From comparators to timers (TIM1/2/3/4/15/16/17)

Purpose

The comparators (COMP1/2) output values can be connected to timers (TIM1/2/3/4/15/16/17) input captures, TIMx_ETR or timer break signals. The connection to ETR is described in *Section 35.3.6: External trigger input*.

Comparators (COMP1/2) output values can also generate break input signals for timers (such as TIM1). The sources for break (tim_brk) channel are one of the following:

- external: connected to one of the TIMx_BKIN pin (as per selection done in the AFIO controller) with polarity selection and optional digital filtering
- internal: coming from comparators, tim_brk_cmpx input (refer to *Table 342: TIM internal input/output signals* for product specific implementation).

Triggering signals

The tim_etr and tim_brk signals connected TIM1 (coming from COMP1/2) are given in:

- tim_etr (*Table 348: Interconnect to the tim_etr input multiplexer*): external trigger internal input bus

These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulse width control.

- tim_brk (*Table 349: Timer break interconnect* and *Table 350: Timer break2 interconnect*)
- *Section 35.3.6: External trigger input*
- *Section 35.3.18: Using the break function*

For TIM2/3/4, the sources connected to the tim_ti[1:4] input multiplexers coming from comparators and some other peripherals, are given in:

- *Table 367: Interconnect to the tim_ti1 input multiplexer*
- *Table 368: Interconnect to the tim_ti2 input multiplexer*
- *Table 370: Interconnect to the tim_ti4 input multiplexer*
- *Table 372: Interconnect to the tim_etr input multiplexer*
- *Table 373: Interconnect to the tim_ocref_clr input multiplexer*
- *Section 36.4.22: Timers and external trigger synchronization*
- TIMx_TISEL

For TIM15/16/17, the sources connected to timers coming from comparators and other peripherals are given in:

- *Table 392: Interconnect to the tim_ti2 input multiplexer*
- *Table 394: Timer break interconnect*
- *Table 396: Interconnect to the ocref_clr input multiplexer*
- *Section 38.4.15: Using the break function*
- *Section 38.4.23: External trigger synchronization (TIM15 only)*

Active power mode

Run, Sleep, and wake-up capability in Stop 0, Stop 1, and Stop 2 modes for trigger sources. Input and break remain active in same low-power modes as timers activity, on Run and Sleep modes.

14.3.13 System errors as break signals to timers

From system errors to timers (TIM1/15/16/17)

Purpose

CSS, CPU lockup, SRAM2 parity errors, ECC double errors, FLASH ECC double-error detection, and PVD can generate system errors in the form of timer break toward timers (TIM1/15/16/17).

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

Triggering signals

The possible sources of break are described in:

- *Section 35.3.18: Using the break function* for TIM1
- *Section 38.4.15: Using the break function* for TIM15/16/17
- *Table 351: System break interconnect* for TIM1
- *Table 395: System break interconnect* for TIM15/16/17

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 360: Effect of low-power modes on TIM1*
- *Table 379: Effect of low-power modes on TIM2/TIM3/TIM4*
- *Table 400: Effect of low-power modes on TIM15/TIM16/TIM17*

14.3.14 Timers generating IRTIM signal

From timers (TIM16/17) to IRTIM

The general-purpose timer (TIM16/TIM17) output channels TIMx_OC1 and USART1/UART4 TX output, are used to generate the waveform of the infrared signal output.

This functionality is described in *Section 40: Infrared interface (IRTIM)*.

14.3.15 Triggers for communication peripherals

From LP timers (LPTIM1/2/3), comparators (COMP1/2), GPDMA1 transfer complete, EXTI, RTC alarm and RTC wake-up to USART1/3, UART4/UART5, LPUART1, I2C1/2, I3C1/2, and SPI1/2

Purpose

LP timer (LPTIM1/2/3) output channels (lptim1_ch1, lptim1_ch2 and lptim3_ch1), timers (tim15_trgo_cktim, tim16_oc1), comparator (COMP1/2) output channels (comp1_out and comp2_out),

EXTI, RTC alarm and RTC wakeup, can be used as trigger to start a communication on the selected USART, UART, LPUART, I2C, I3C, or SPI peripherals.

A GPDMA1 transfer complete can trigger both the GPDMA1 regular or linked-list new transfers and communication on selected communication peripheral.

Triggering signals

The outputs from triggers are directly connected to peripheral trigger inputs.

The selection of input triggers is detailed in:

- *Table 495: USART interconnection (USART1/3 and UART4/5)*
- *Table 507: LPUART interconnections (LPUART1)*
- *Table 457: Trigger interconnections* for I2C peripherals
- *Table 477: I3C triggers, when I3C as controller* for I3C peripherals

The outputs (from timer) are directly connected to SPI1/2 inputs on signals spi_itrx (x = 6, 7). The selection of input triggers on SPI is provided in:

- *Section : Description of SPI interconnections*

Active power mode

These interconnections remain active in Run, Sleep, and Stop modes if both source and communication line are autonomous under the mode. Refer to:

- *Section 47.6: USART in low-power modes*
- *Section 45.5: I2C in low-power modes*
- *Section 49.6: SPI in low-power modes*
- *Section 46.14: I3C in low-power modes*

14.3.16 Triggers to GPDMA

From EXTI, RTC (alarm/wakeup), TAMP (TAMP1/2/3), timers (TIM2/15), LP timers (LPTIM1/3/4), comparators (COMP1/2), GPDMA1 transfer complete (gpdma1_chx_tc), ADC1/2 and analog watchdog to GPDMA1

Purpose

A GPDMA trigger can be assigned to a GPDMA channel x. A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- *Section 15.3.6: GPDMA triggers*
- *Section 15.4.12: GPDMA triggered transfer*
- GPDMA_CxTR2 for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0].
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

GPDMA trigger mapping is specified in *Table 122: Programmed GPDMA1 trigger*, according to GPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

Assuming sources are active down to Stop modes, this interconnection remains functional in Stop 0 and Stop 1 modes for GPDMA.

Refer to:

- *Section 15.6: GPDMA in low-power modes*

14.3.17 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1/2), comparators (COMP1/2) and OPAMP (OPAMP1/2)

Purpose

The internal reference voltage (V_{REFINT}), the internal temperature sensor (V_{TS}), and V_{BAT} monitoring channel are connected to ADC (ADC1/2) input channels. In addition, the internal digital core voltage (V_{CORE}) is connected /to ADC1/2 input channels.

DAC channels (DAC1_OUT1/DAC2_OUT2) and V_{REFINT} are connected to comparators (COMP1/2).

OPAMP1/2 outputs can be connected to ADC1/2 input channels through the GPIO. DAC1_OUT1 can be connected to OPAMP1_VINP. DAC1_OUT2 can be connected to OPAMP2_VINP.

Refer to *Section 23.4.2: DAC pins and internal signals* for:

- dac_out1 analog output DAC channel1, output, for on-chip peripherals
- dac_out2 analog output DAC channel2, output, for on-chip peripherals

This is according to:

- *Section 22.2: ADC main features*, Figure 119. ADC1 connectivity, Figure 120. ADC2 connectivity
- *Section 26.3.3: Signal routing*
- *Section 25.3.2: COMP pins and internal signals*

Active power mode

These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to:

- *Section 22.5: ADC in low-power modes*
- *Section 26.4: OPAMP low-power modes*
- *Section 25.4: COMP in low-power modes*

14.3.18 Clock source for the DAC sample and hold mode

From LSI/LSE to DAC1/2

Purpose

DAC1 can run in Stop mode. The sample and hold block and its associated registers use the LSI or LSE clock source (dac_hold_ck) in Stop mode.

Section 23.4.2: DAC pins and internal signals:

dac_hold_ck (input) - DAC low-power clock used in sample and hold mode

Active power mode

This feature remains available down to Stop 2 mode.

14.3.19 Internal tamper sources

From internal peripherals, clocks to tamper.

Purpose

In order to detect any abnormal activity or tentative to corrupt the device, tampers are introduced and alert the system of such undesired event. Different actions can be taken in consequences.

List of tamper sources can be found in *Table 446: TAMP interconnection*.

Active power mode

This interconnection is active in all power modes if the tamper source is activated.

14.3.20 Output from tamper to RTC

From TAMP to RTC

Purpose

The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.

Refer to *Section 43.3.3: GPIOs controlled by the RTC* for more details.

Active power mode

This interconnection remains active in all power modes.

14.3.21 Encryption keys to AES/SAES

From TAMP backup registers, system flash memory to and in between SAES and AES

Purpose

The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented in order to load them in a non-readable way. Tamper backup registers or system flash memory can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to *Section 32.4.14: SAES operation with wrapped keys* for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to *Section 32.4.15: SAES operation with shared keys* for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.

14.3.22 I3C IBI acknowledge to timers from I3C1/2 to TIM15/16/17 and LPTIM1/2/3

Purpose

The I3C peripherals generate an IBI acknowledge event when peripheral acts as controller, for timing control with asynchronous mode 0. This enables to timestamp the moment at which the target(s) acquired sampled data and to time-correlate them.

Refer to *Section 46.9.13: I3C IBI transfer, as controller/target* for more details.

Active power mode

Timers are functional in Run and Sleep modes. I3C is functional in Run, Sleep, Stop 0, and Stop 1 modes, and so are functional LP timers.

15 General purpose direct memory access controller (GPDMA)

15.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

15.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 12 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 15.3.1*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers

  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 15.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
  - Channel abort and restart
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and nonsecure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a nonsecure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

15.3 GPDMA implementation

15.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 116. GPDMA1 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 7	2	0	Channel x (x = 0 to 7) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and SRAM.
x = 8 to 9	4	0	Channel x (x = 8 to 9) is implemented with: – a FIFO of 32 bytes, 8 words – fixed/contiguously incremented addressing
x = 10 to 11	4	1	Channel x (x = 10 to 11) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be also used for GPDMA transfers between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

15.3.2 GPDMA in low-power modes

The GPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 117. GPDMA1 wake-up in low-power modes

Feature	Low-power modes
Wake-up	GPDMA1 in Sleep mode

15.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[6:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

15.3.4 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 119. Programmed GPDMA1 request as a block request

15.3.5 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 120. GPDMA1 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0 and x = 1

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the GPDMA has transferred the whole block (see *Section 15.4.14* for more details).

Table 121. Programmed GPDMA1 request with peripheral early termination

15.3.6 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

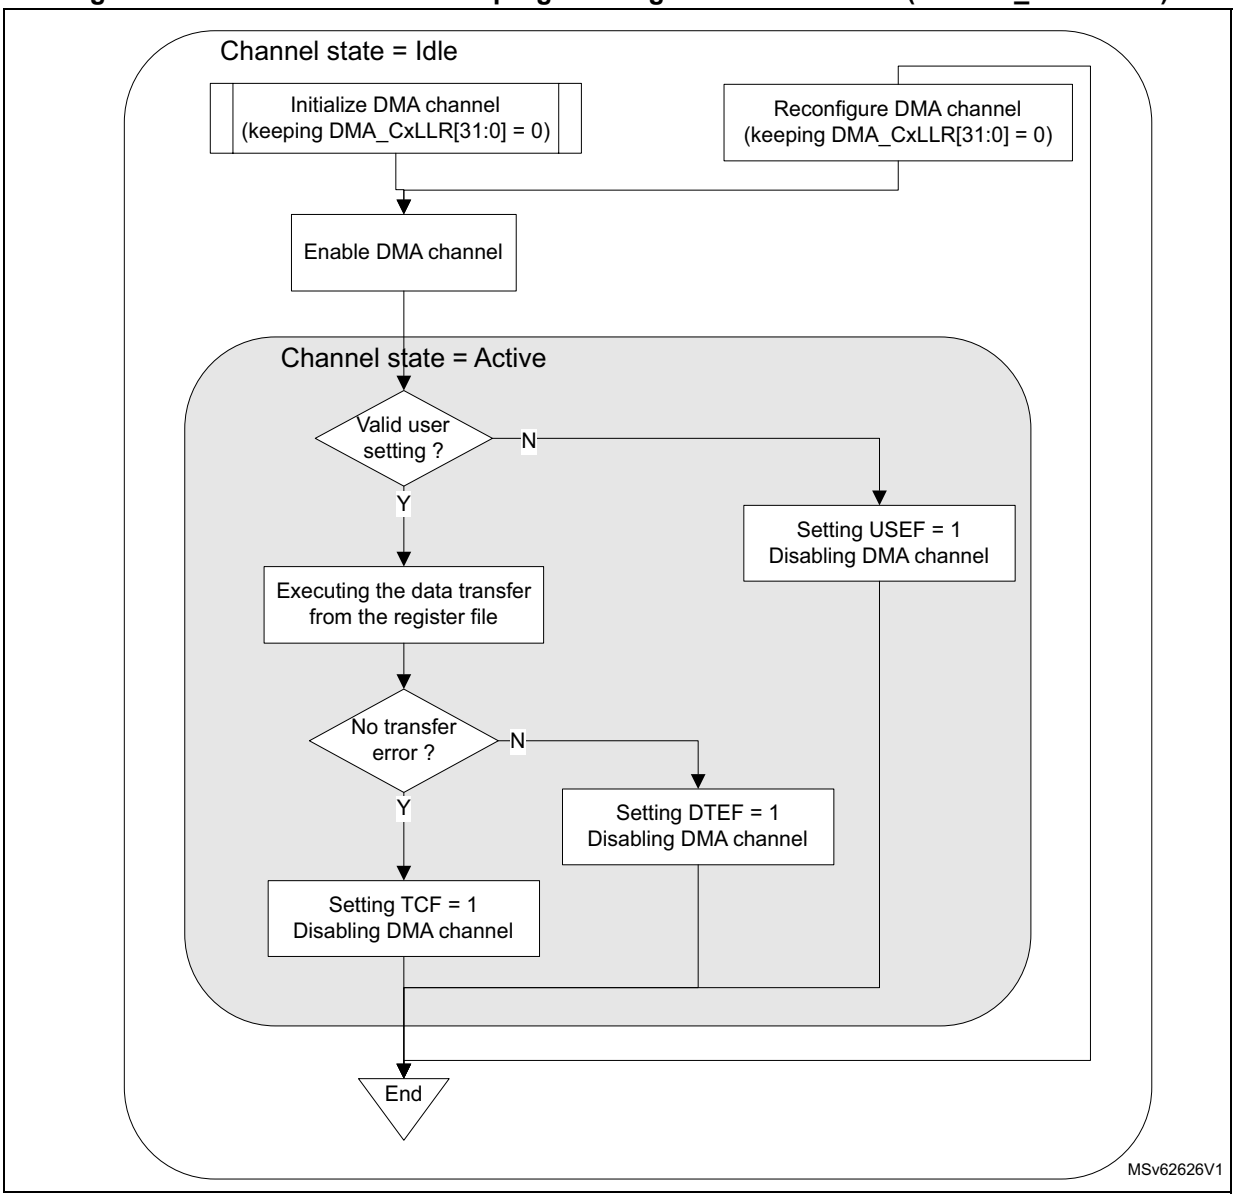
15.4 GPDMA functional description

15.4.1 GPDMA block diagram

Figure 40. GPDMA block diagram



15.4.2 GPDMA channel state and direct programming without any linked-list

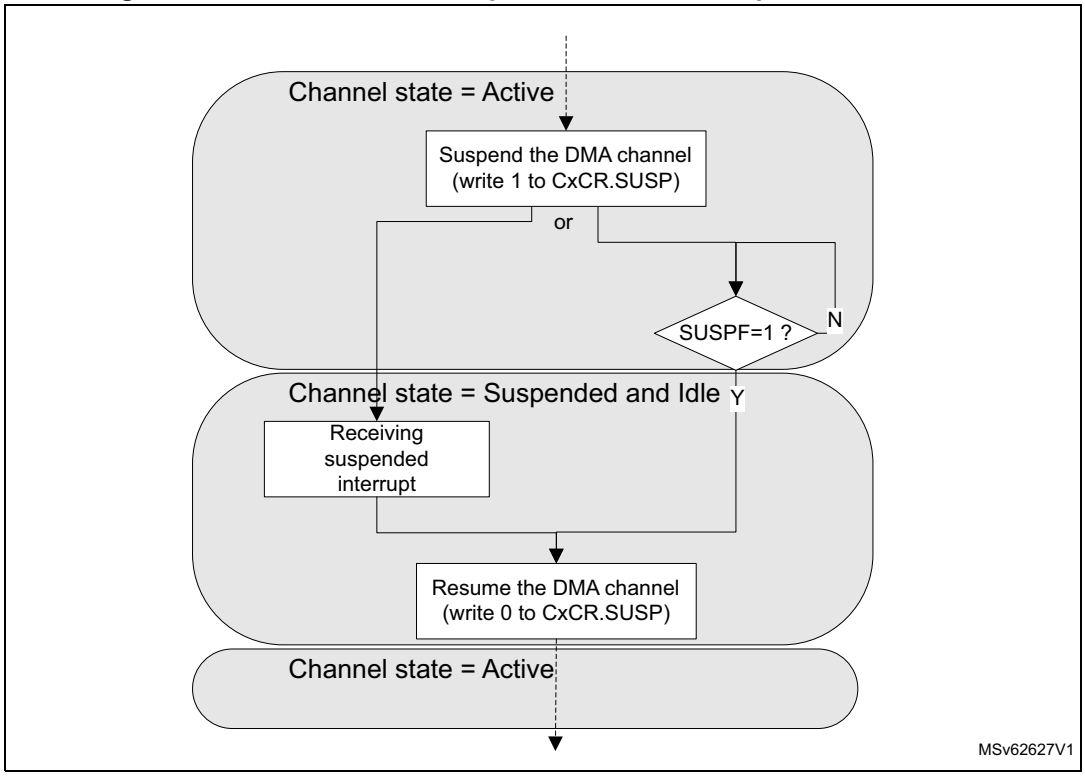
After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

Figure 41 illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 41. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)

15.4.3 GPDMA channel suspend and resume



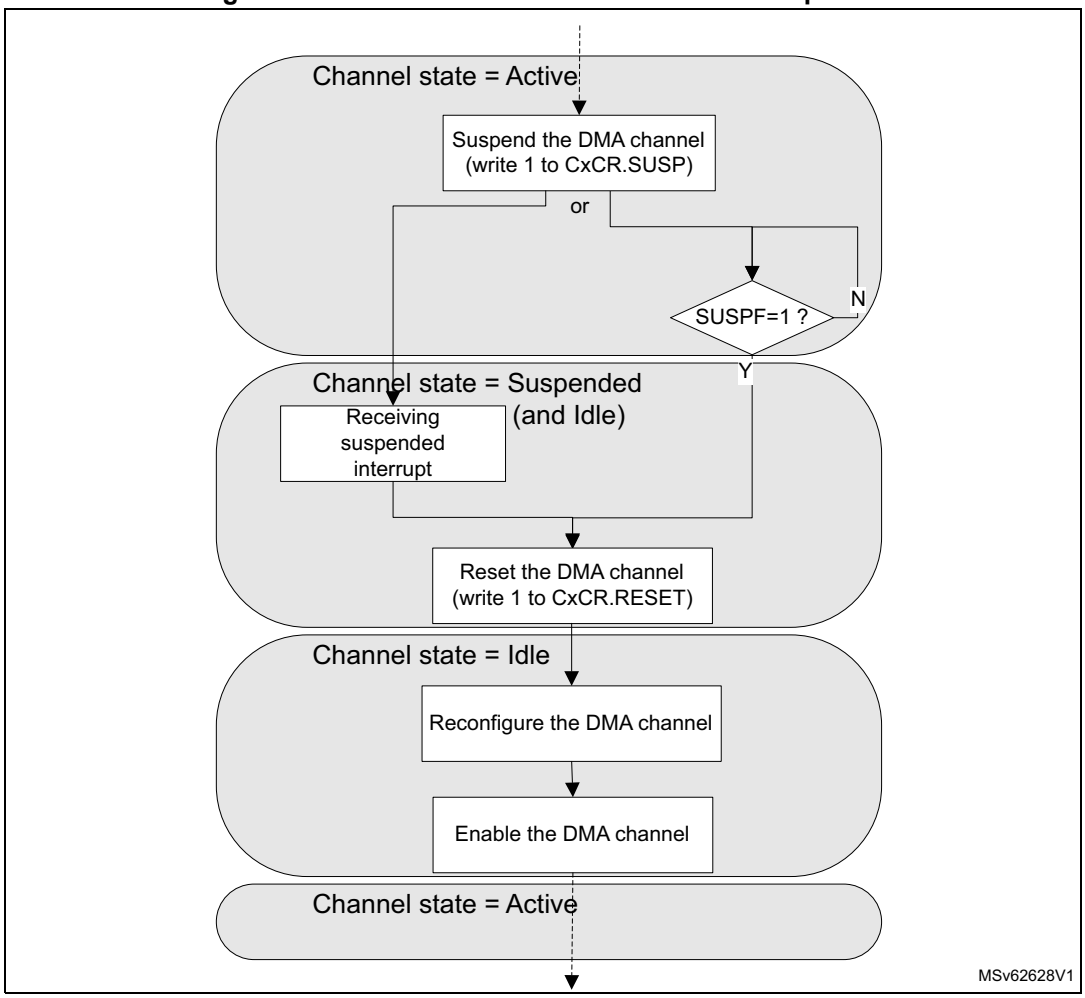
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note: An ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 42. GPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

15.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 43. GPDMA channel abort and restart sequence

15.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the

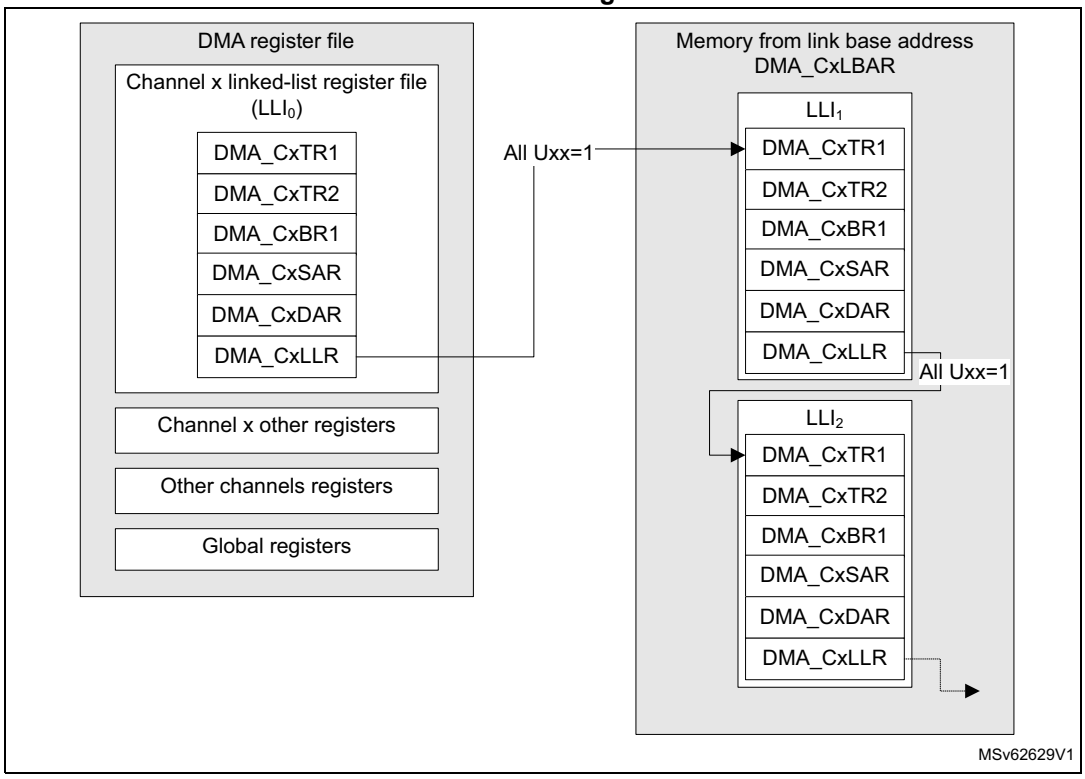
GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 9) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 44*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x (x = 10 to 11), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see *Figure 45*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 44. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



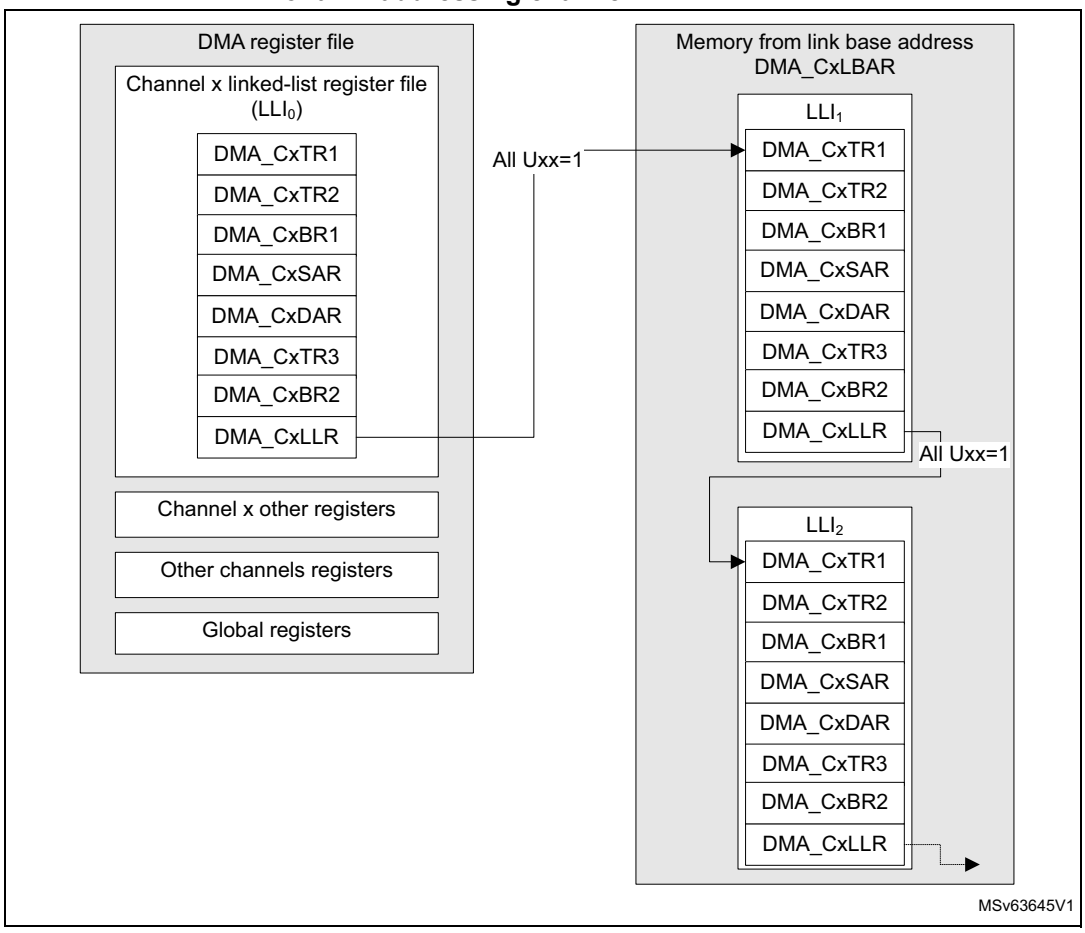


Figure 45. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

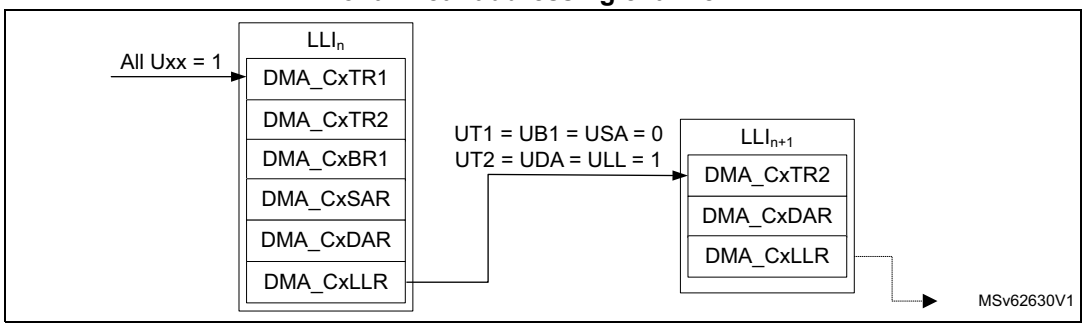
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 46*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 47*.

Figure 46. GPDMA dynamic linked-list data structure of a linear addressing channel x



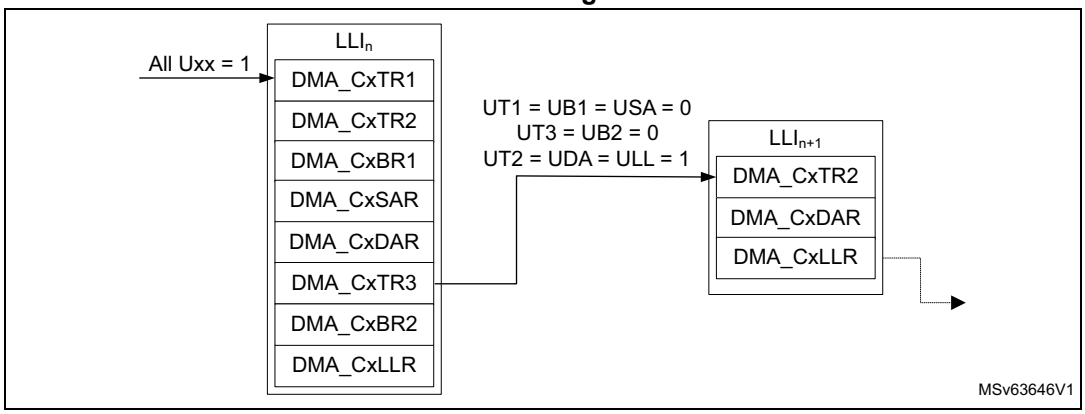


Figure 47. GPDMA dynamic linked-list data structure of a 2D addressing channel x

The user must program GPDMA_CxLLR for each LLI_n to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

15.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

15.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

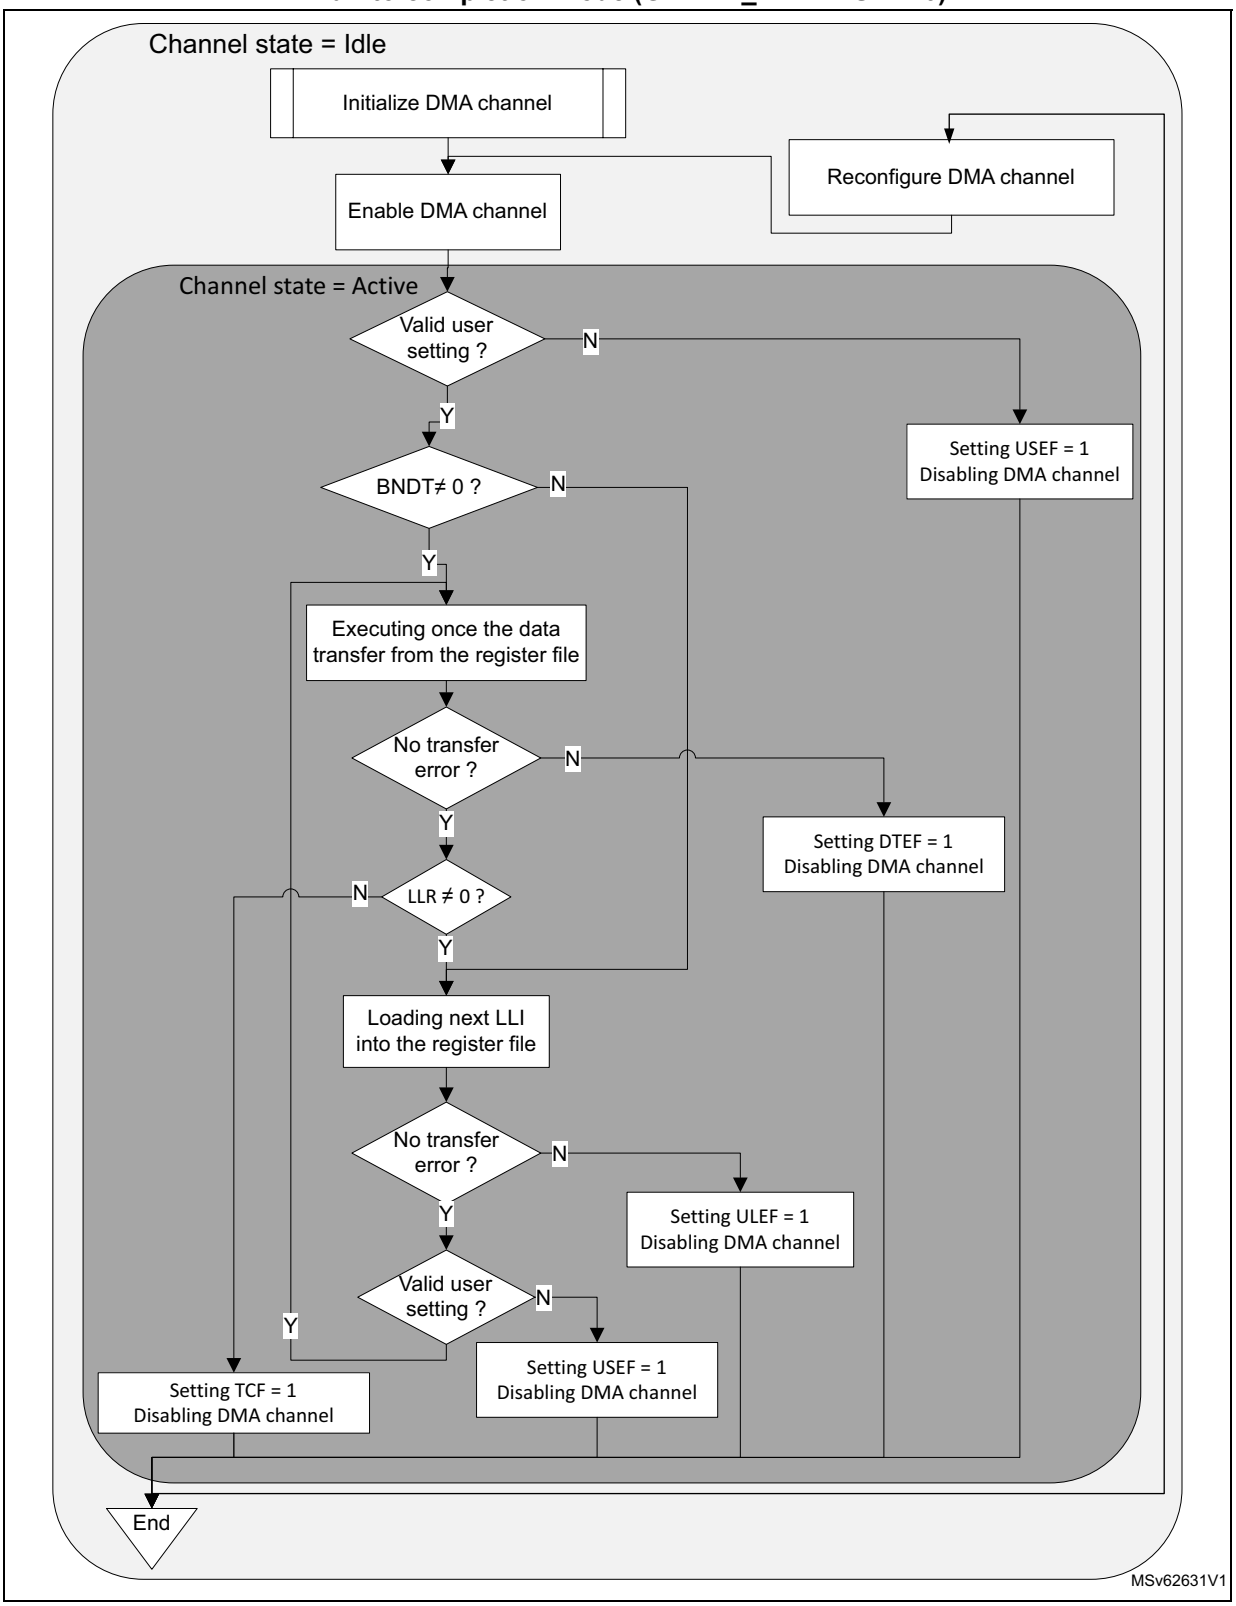
GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 15.4.14* for more details).



In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 48 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

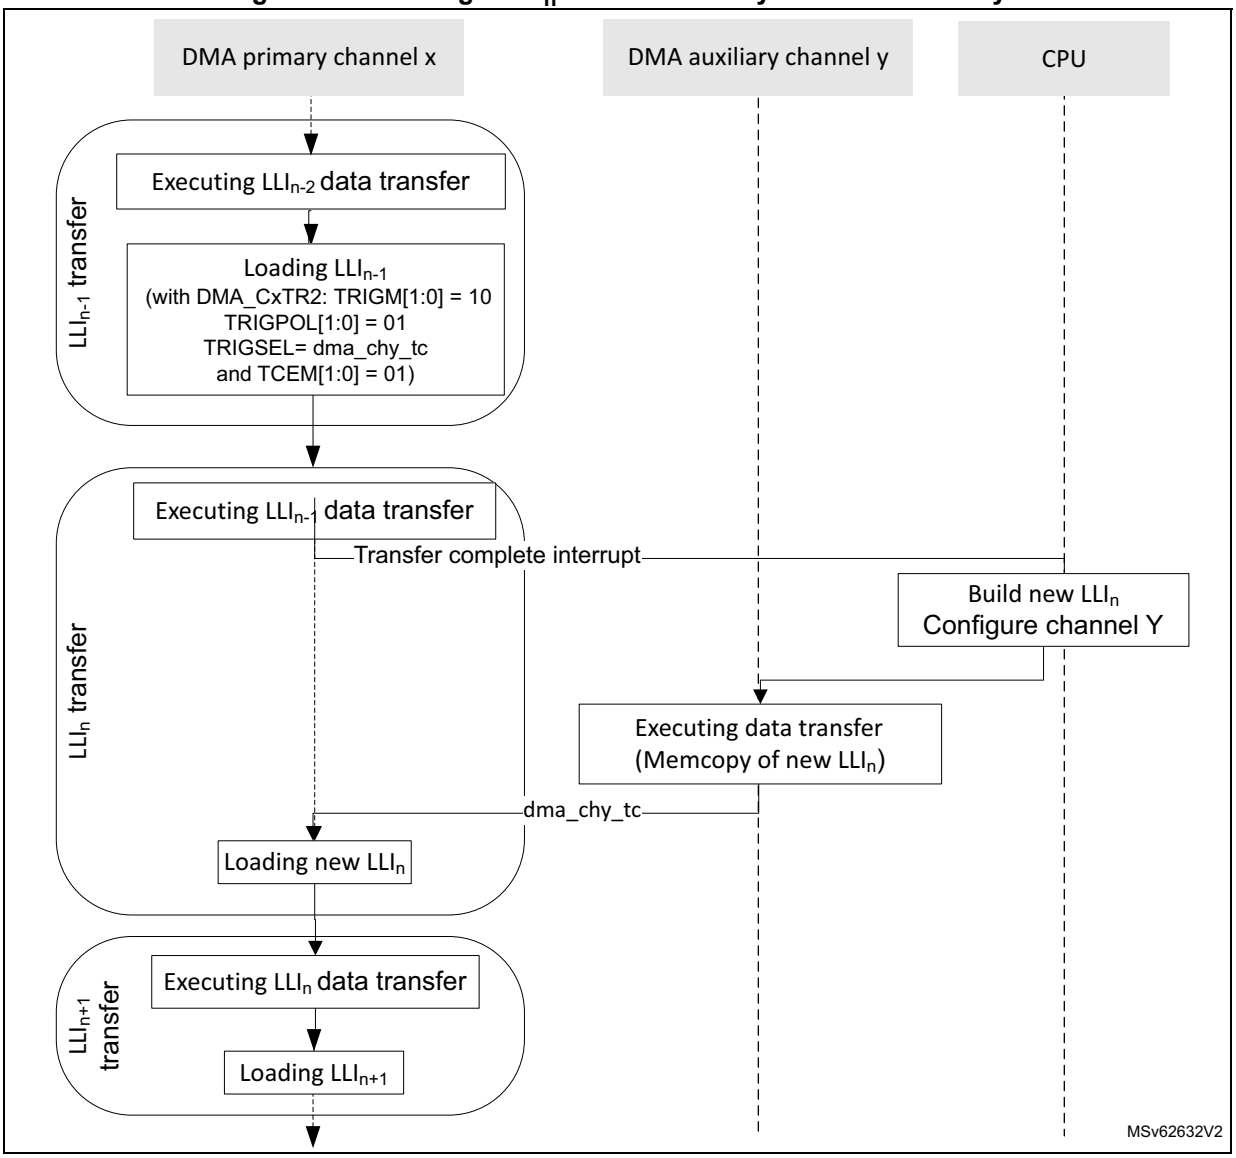
Note: Figure 48 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 48, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 15.3.5).

Figure 48. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 15.3.6* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 49 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 49. Inserting a LLI_n with an auxiliary GPDMA channel y

15.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

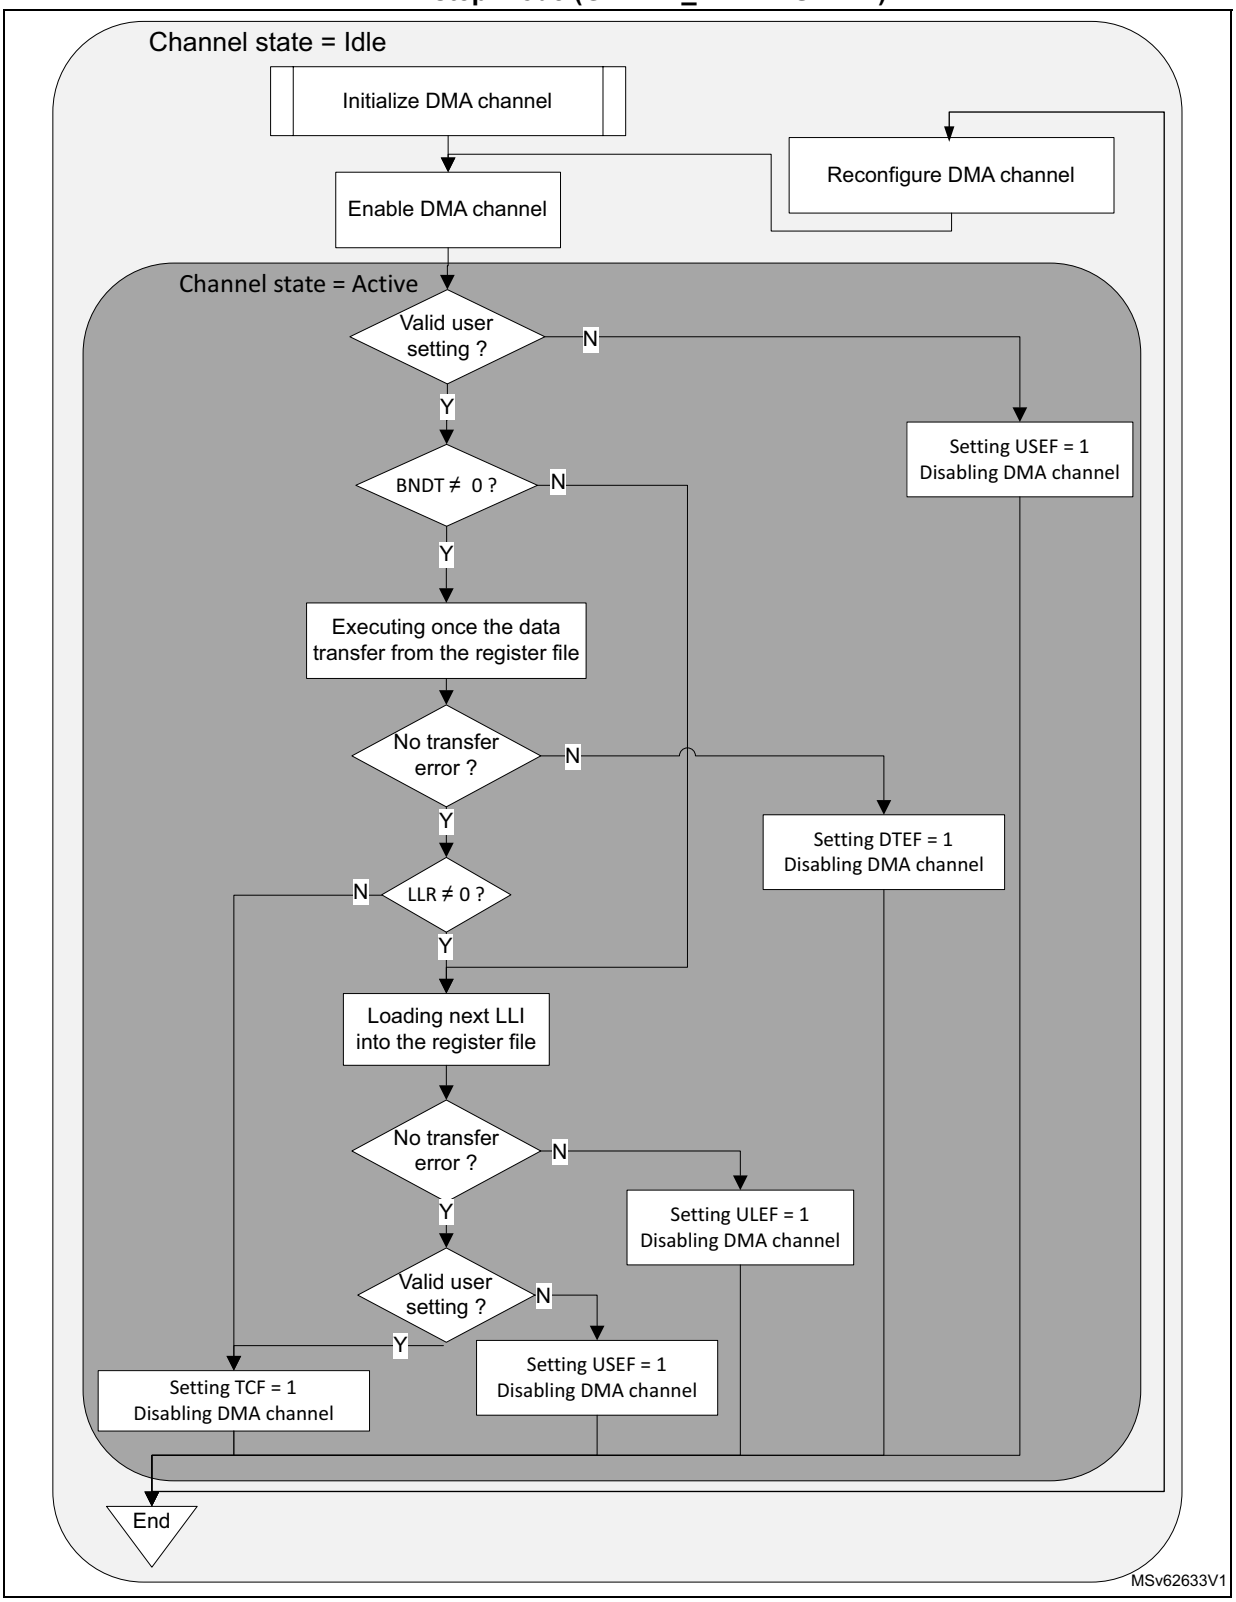
A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 10 to 11), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 10 to 11) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 10 to 11) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 15.4.14* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 50 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 50 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 50, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 15.3.5).

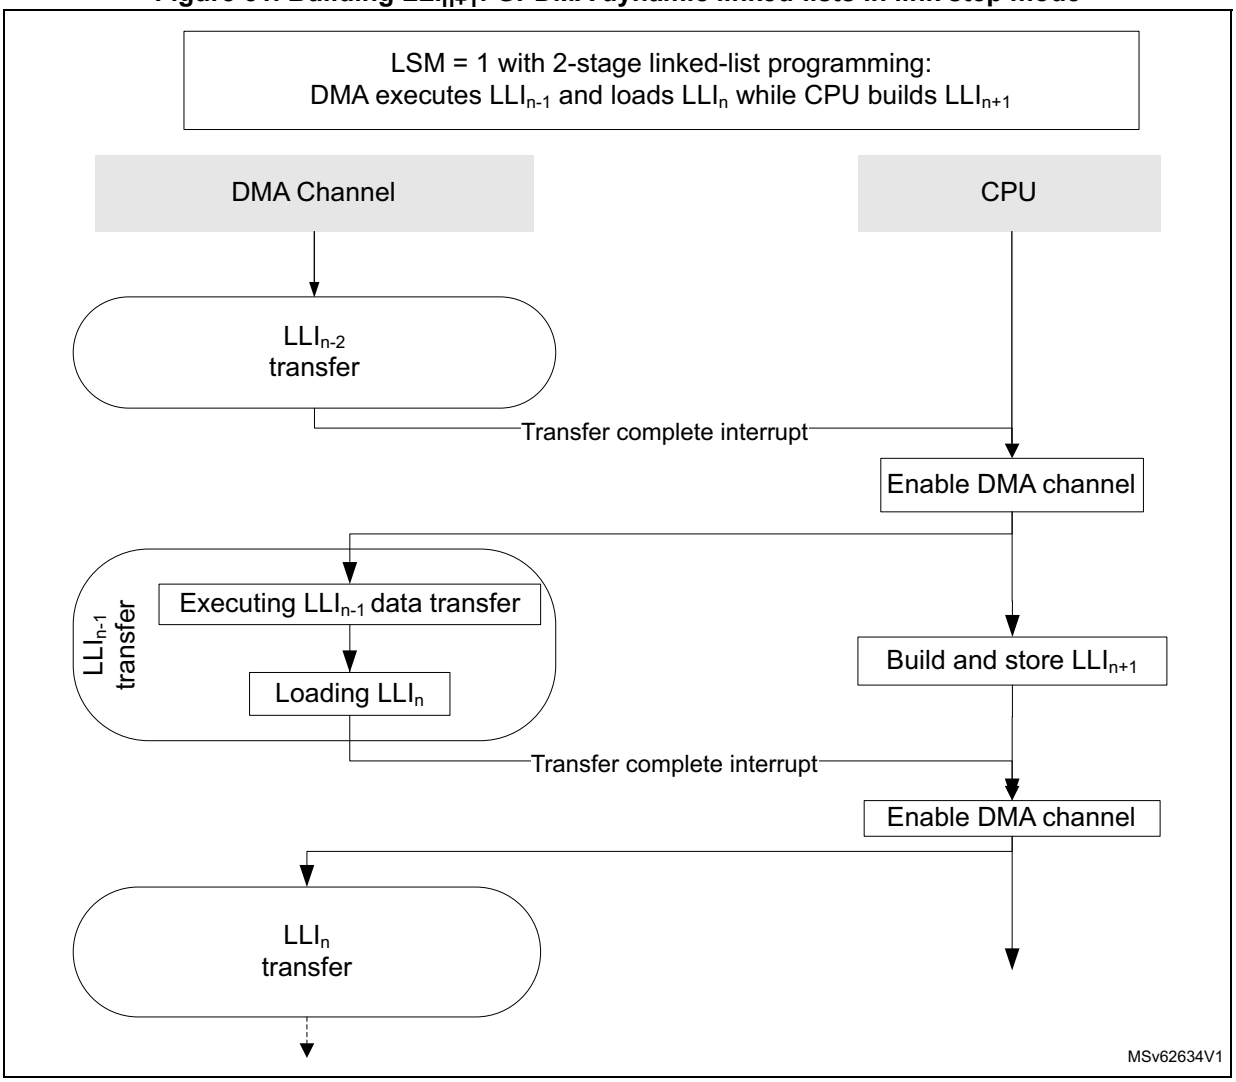


Figure 50. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in *Figure 51*.

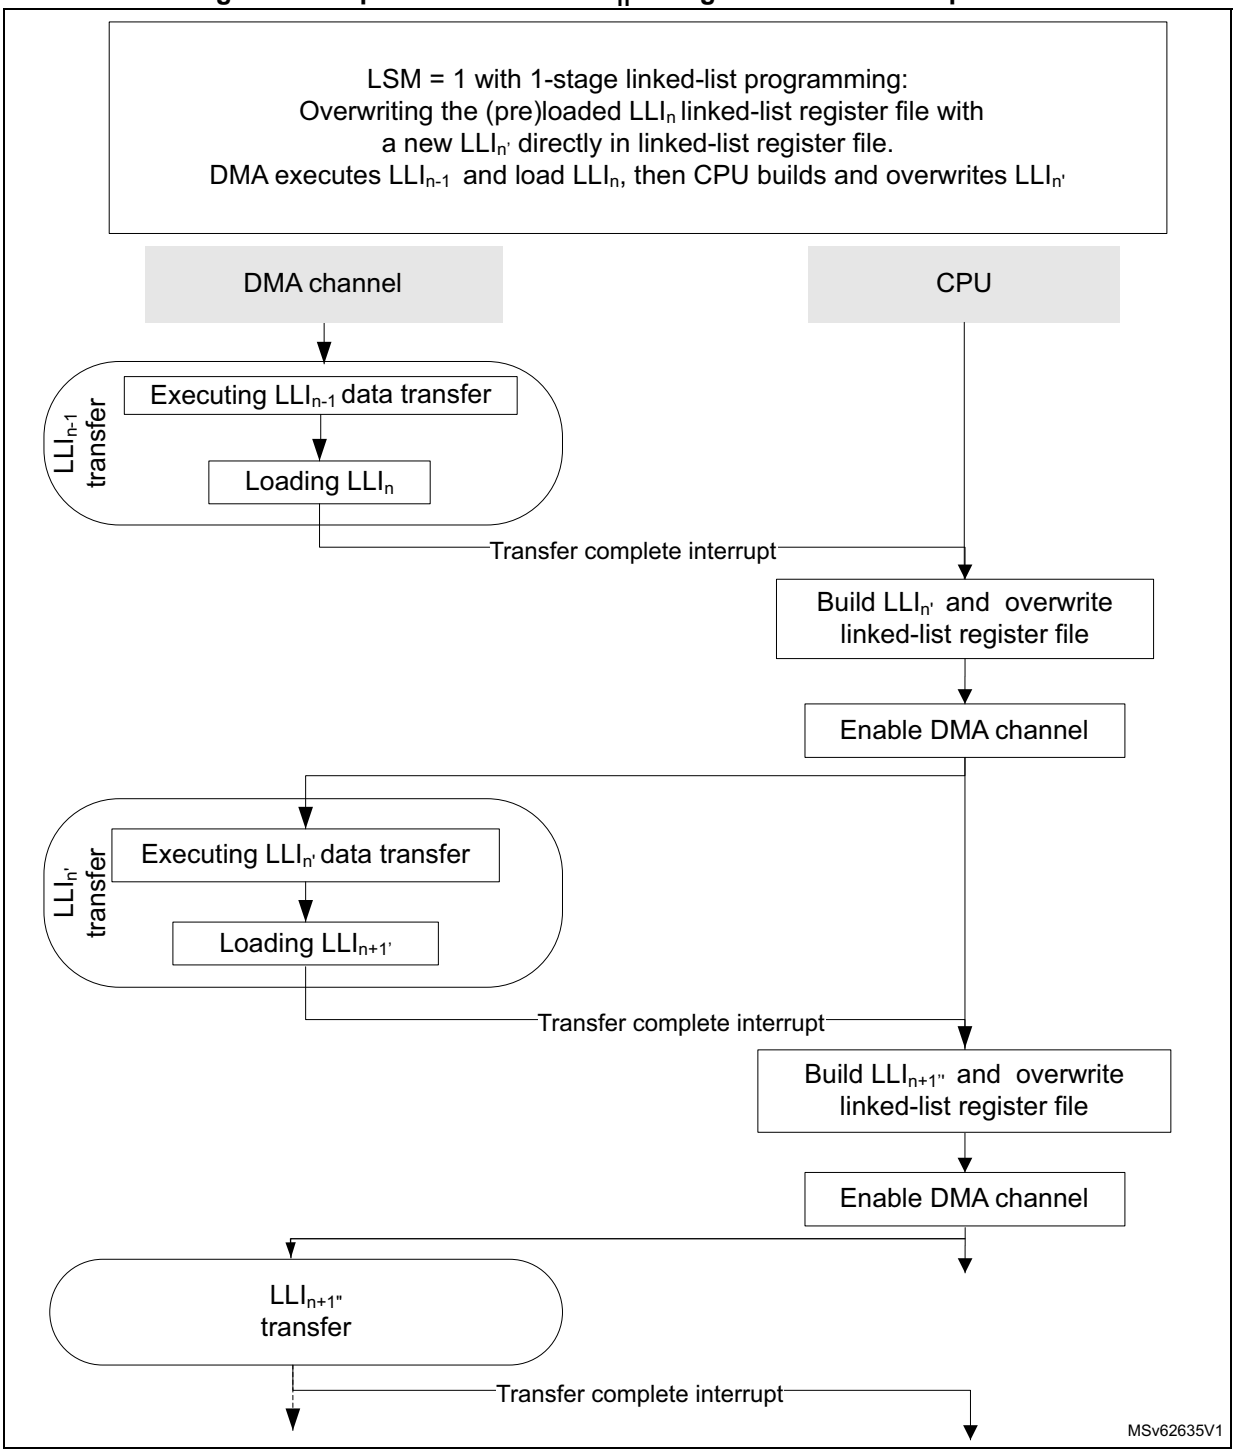

Figure 51. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode

Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new $LLI_{n'}$, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new $LLI_{n'}$, as shown in *Figure 52*.

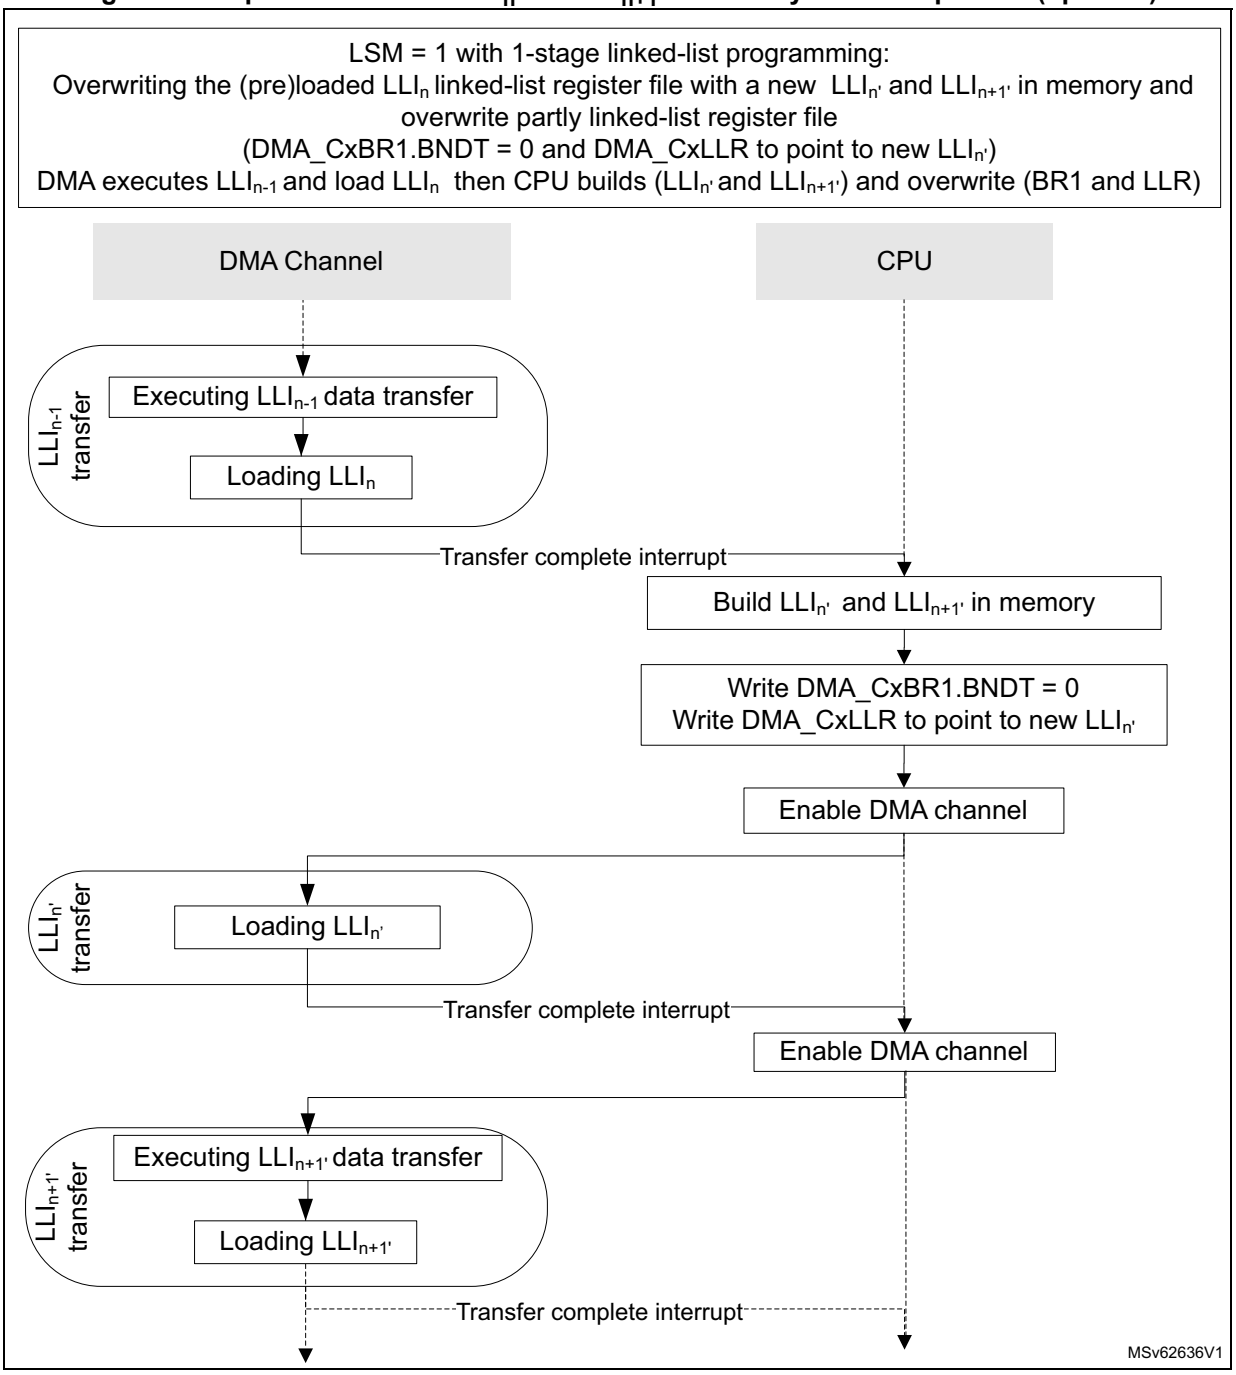

Figure 52. Replace with a new $LLI_{n'}$ in register file in link step mode

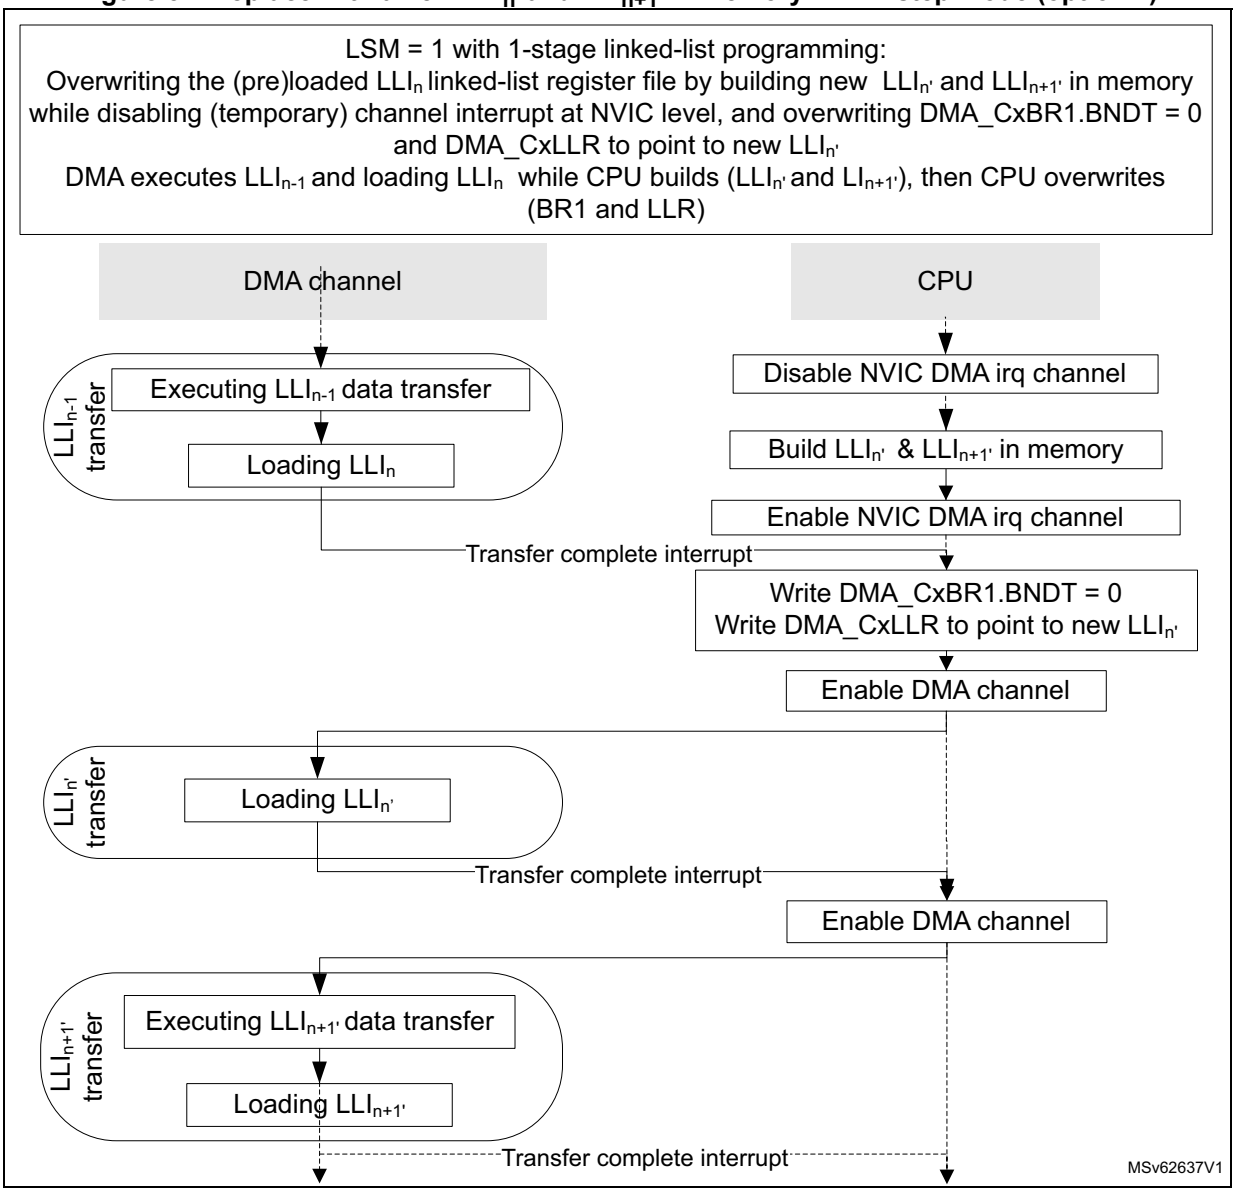
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in *Figure 53*.

Figure 53. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 54*.

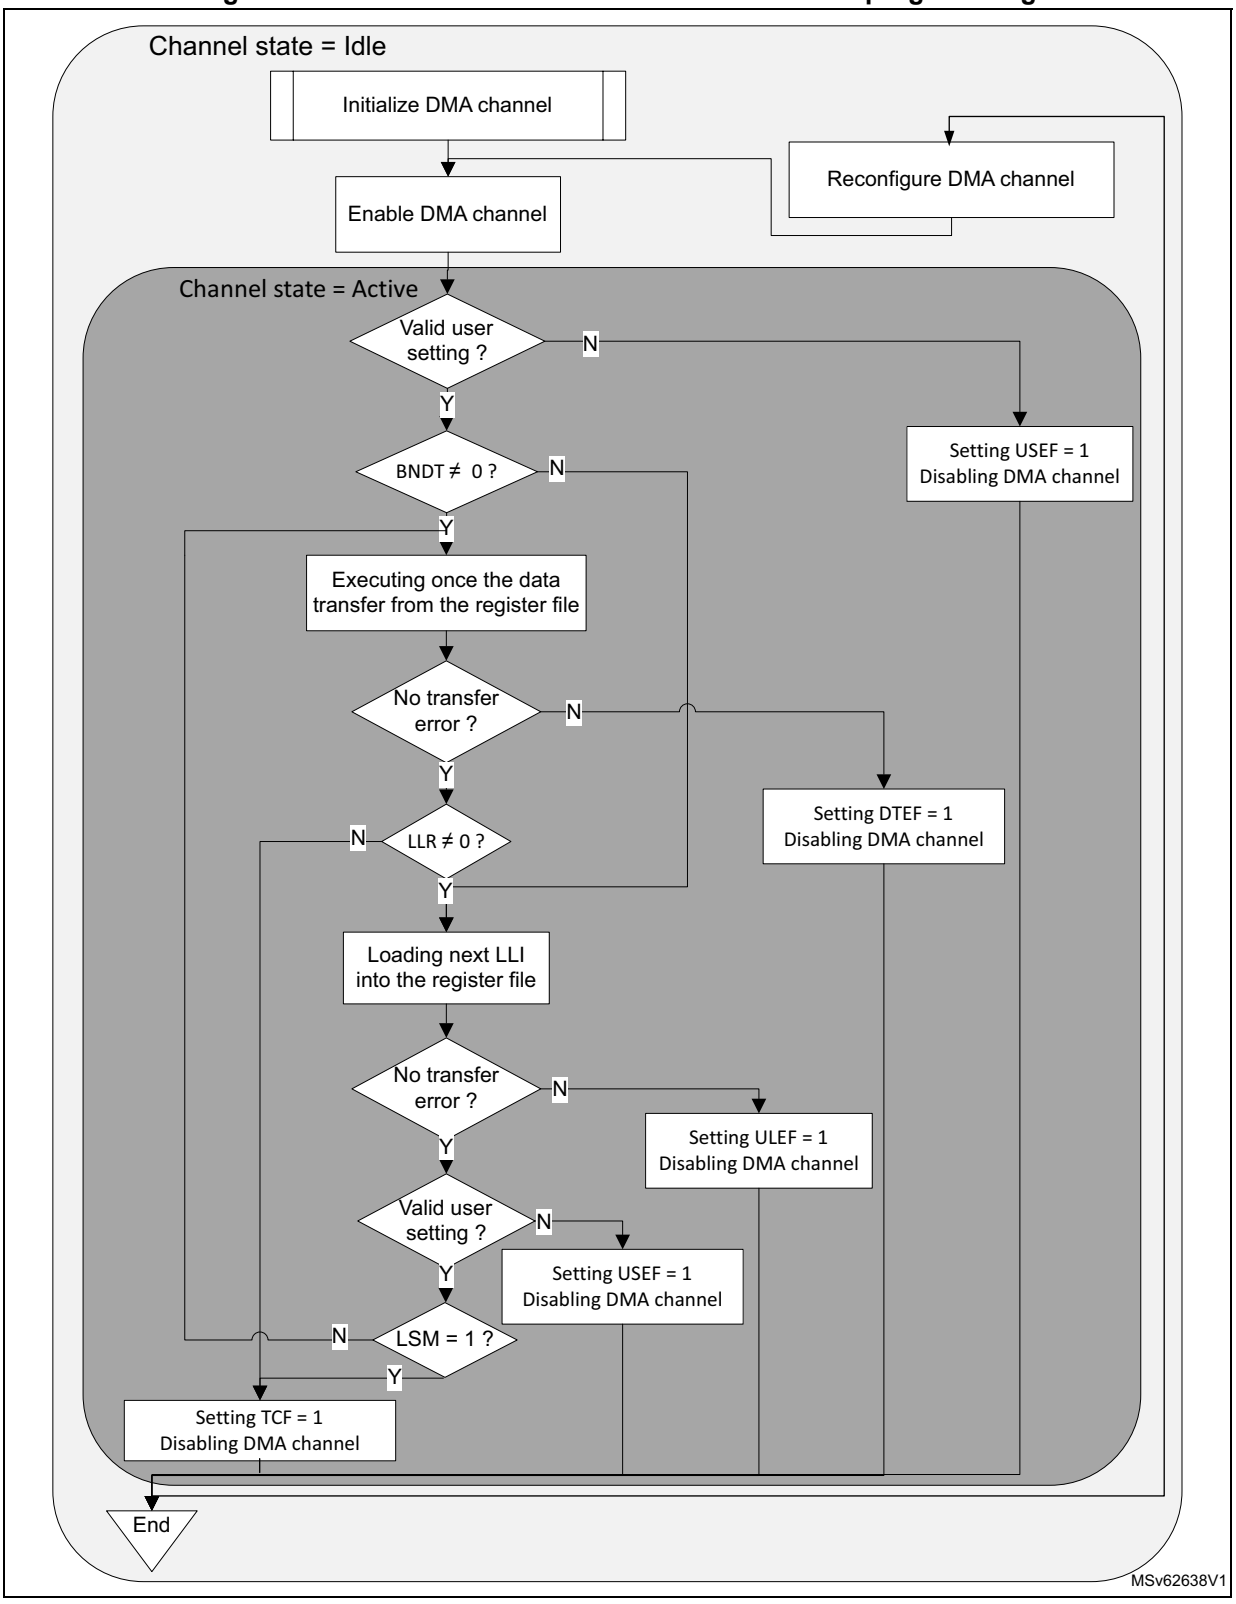
Figure 54. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

15.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 15.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 55 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 55 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 55, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 15.3.5).

Figure 55. GPDMA channel execution and linked-list programming

15.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 15.3.1* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

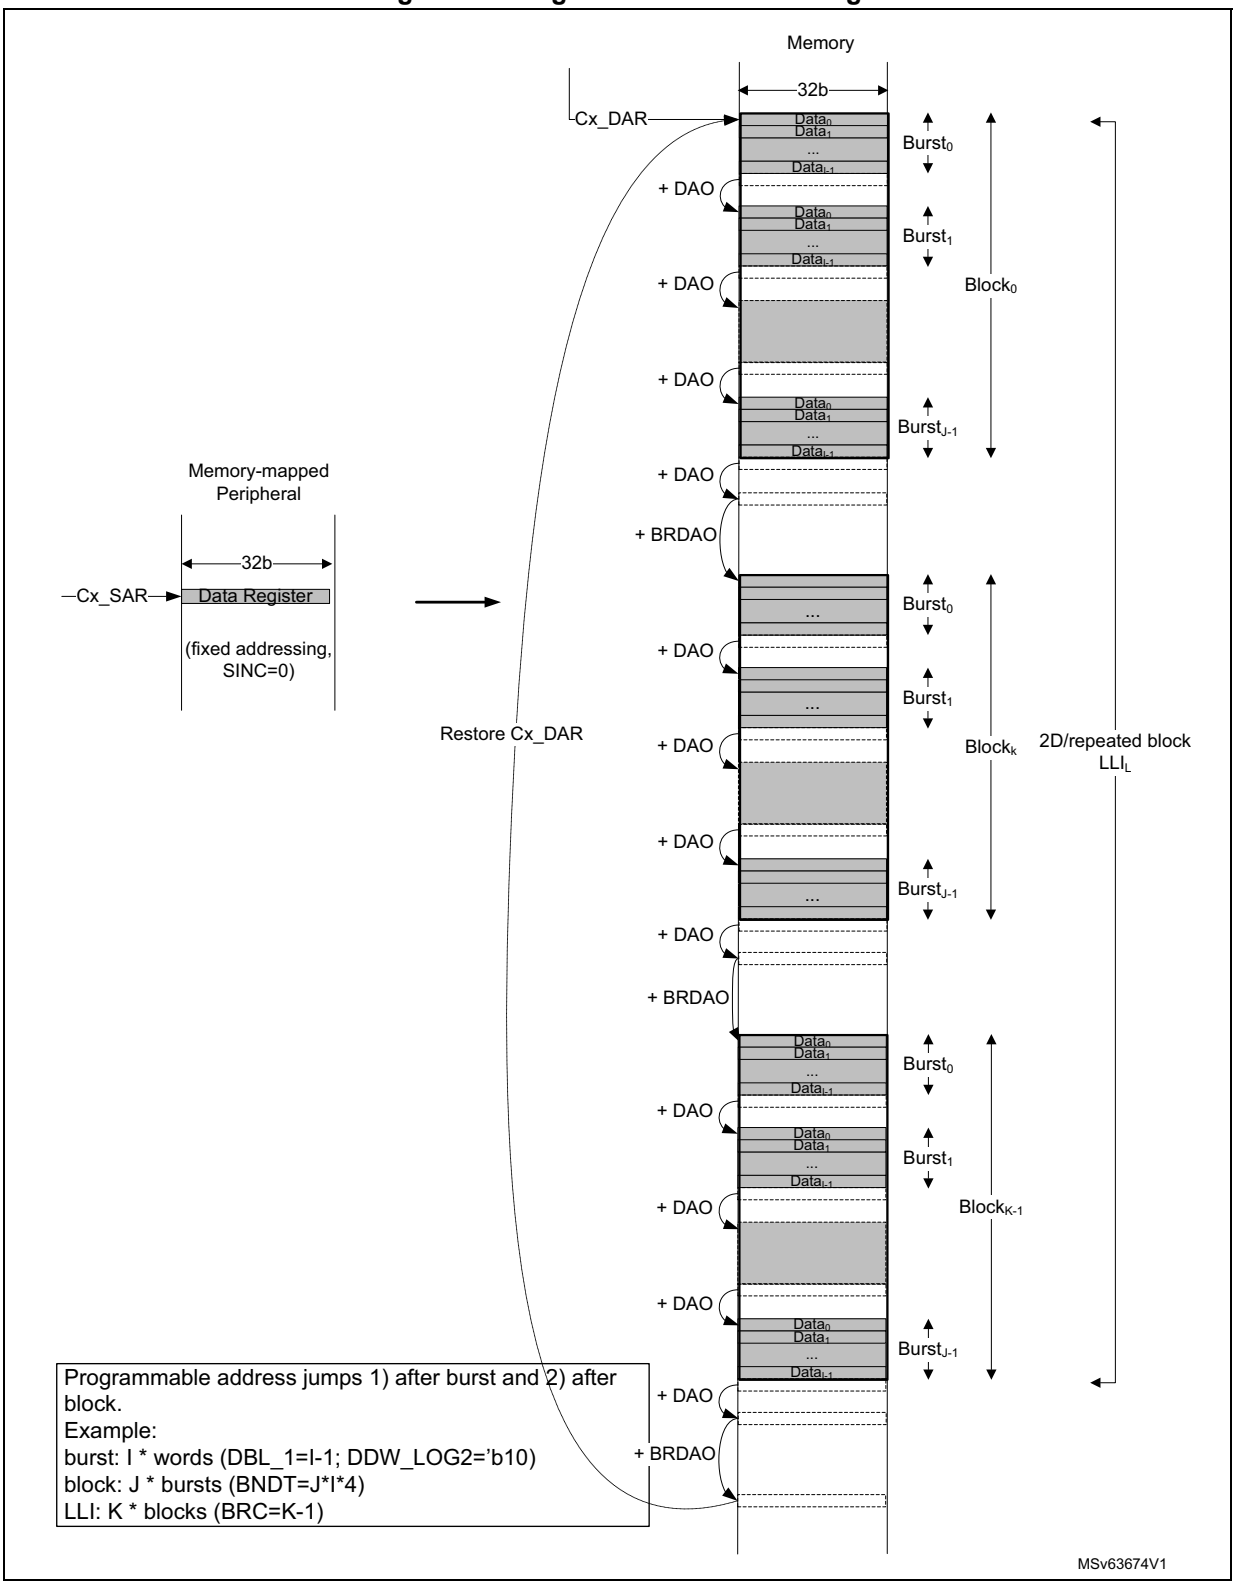
The table below lists the main characteristics of a GPDMA burst.

Table 123. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



GPDMA burst with 2D addressing (channel x = 10 to 11)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 56* with a 2D destination buffer.

Figure 56. Programmed 2D addressing

GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the half of the FIFO size of the channel x, in bytes (see *Section 15.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see *Table 124*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 124. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)

							1		$B_4B_6B_5B_7,B_0B_2B_1B_3$

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

15.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see *Section 15.3.3*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[6:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

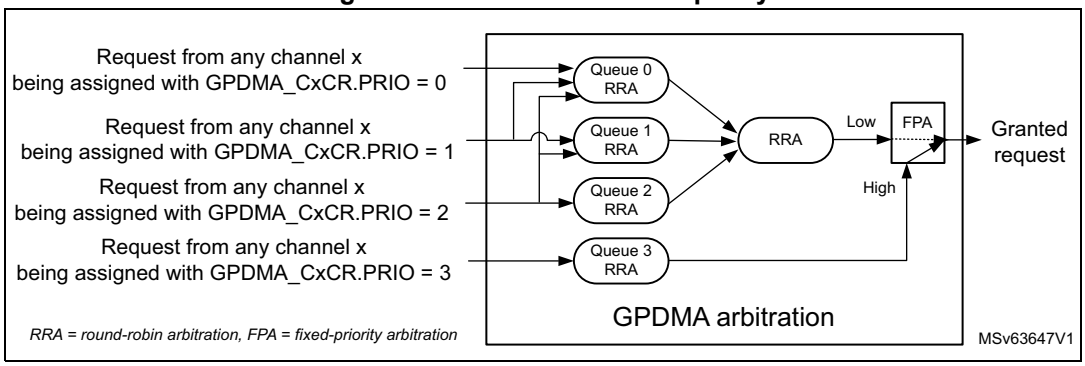
An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 57*, is defined by:



- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1, or 2) for non time-sensitive channels with priority 0, 1, or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1, or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1, and queue 2.

Figure 57. GPDMA arbitration policy

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

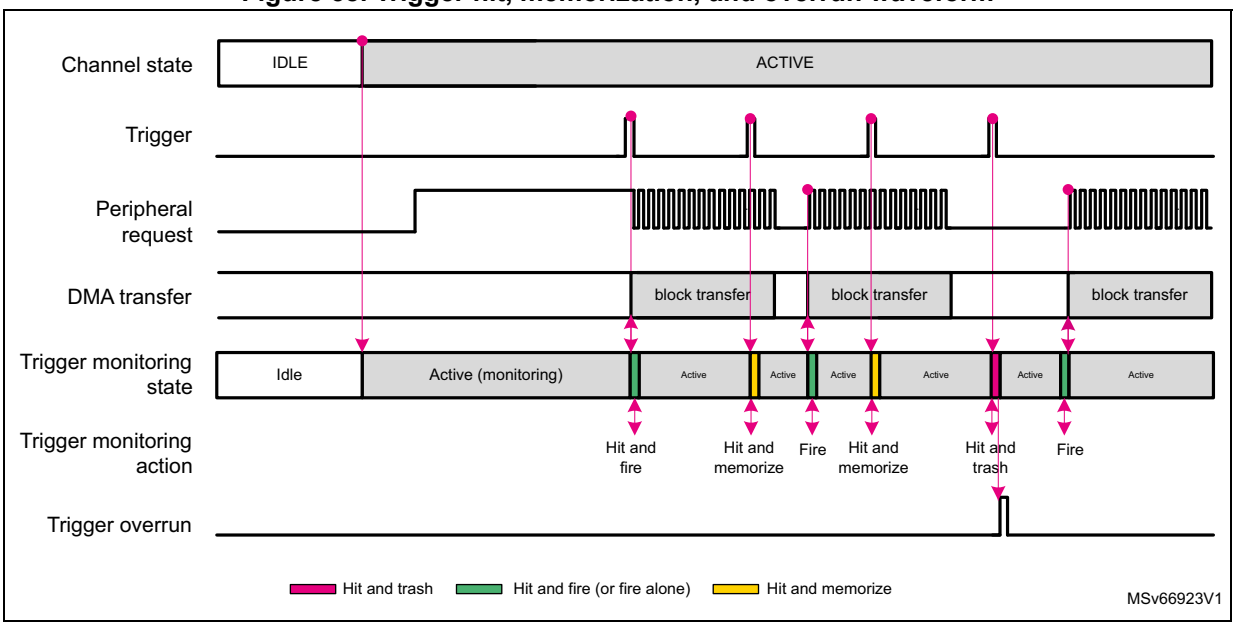
15.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 15.3.6* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 10 to 11), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

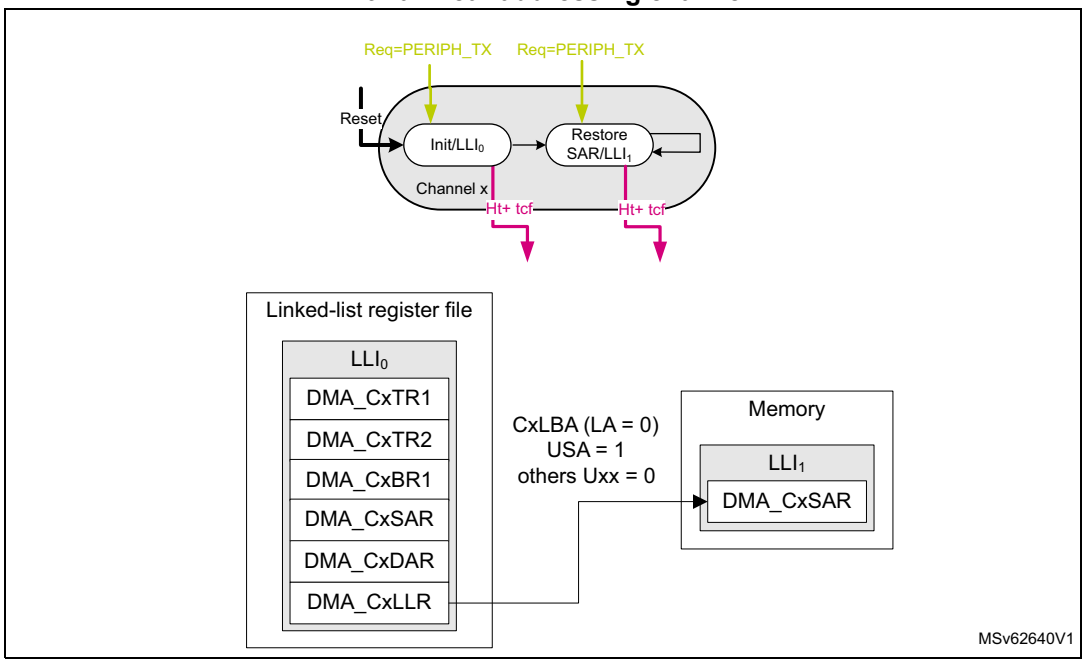
Figure 58 illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 58. Trigger hit, memorization, and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

15.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel



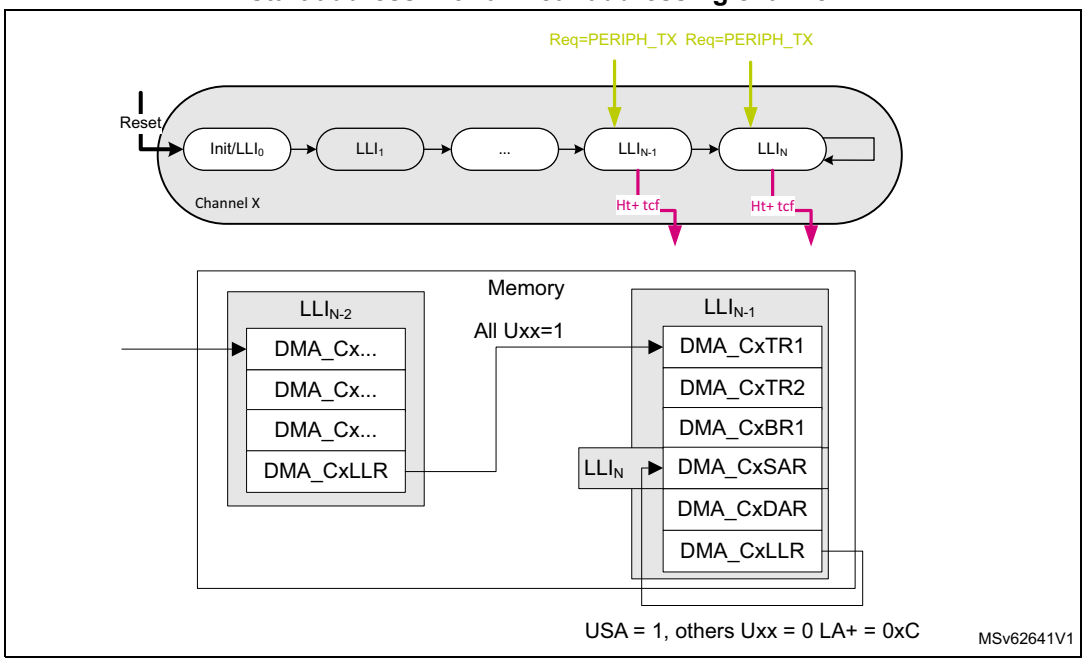
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

Figure 59 illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 59. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

Figure 60 illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 60. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

15.4.14 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 15.3.5*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

15.4.15 GPDMA secure/nonsecure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel x is a secure or a nonsecure hardware resource, as configured by GPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or nonsecure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each GPDMA channel x.

The GPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

15.4.16 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR, and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

15.4.17 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single or a burst) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a GPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 10 to 11): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 10 to 11): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 10 to 11): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])

- for channel x (x = 10 to 11): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
- a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
- a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

15.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

15.6 GPDMA in low-power modes

Table 125. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode.
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 15.3.2* to know if any Stop mode is supported.

15.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 126. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 15.4.17*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

15.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

15.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **SECx**: secure state of channel x (x = 11 to 0)
0: Nonsecure
1: Secure

15.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

This register can mix secure and nonsecure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **PRIVx**: privileged state of channel x (x = 11 to 0)
0: unprivileged
1: privileged

15.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock, for example at boot time, the secure privileged attributes of any GPDMA

channel/resource (to lock the setting of GPDMA_CxSECCFGR and GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

				rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **LOCKx**: lock the configuration of GPDMA_SECCFGR.SECx and GPDMA_PRIVCFGR.PRIVx, until a global GPDMA reset (x = 11 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

15.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bit fields returning zero.

				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **MISx**: masked interrupt status of channel x (x = 11 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

15.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **MISx**: masked interrupt status of the secure channel x (x = 11 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

15.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

15.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

15.8.8 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or nonsecure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]

	r	r	r	r	r	r	r								r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level
Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag
0: no half transfer event
1: a half transfer event occurred
A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

15.8.9 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	Res.	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 42*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 43*).
0: no channel reset
1: channel reset

Bit 0 **EN:** enable
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).
Else, this bit can be asserted by software.
Writing 0 into this EN bit is ignored.
0: write: ignored, read: channel disabled
1: write: enable channel, read: channel enabled

15.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer to the destination is nonsecure.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and if present address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

When configured in packing mode (PAM[1] = 1 and destination data width different from source data width), a source block size must be a multiple of the destination data width (see GPDMA_CxBR1.BNDT[2:0] versus DDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer from the source is nonsecure.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word
If the source data width is shorter than a word, this bit is ignored.
If the source data width is a word:
0:no byte-based exchange within the unaligned half-word of each source word
1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode
If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.
Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.
Condition: PAM_1
00: source data is transferred as right aligned, padded with 0s up to the destination data width
01: source data is transferred as right aligned, sign extended up to the destination data width
10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer
Condition: PAM_2
00: source data is transferred as right aligned, left-truncated down to the destination data width
01: source data is transferred as left-aligned, right-truncated down to the destination data width
10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63
The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst
0: fixed burst
1: contiguously incremented burst
The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

15.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	Res.	REQSEL[6:0]						
rw	rw		rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (x = 0 to 9), same as 00, channel x (x = 10 to 11), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x = 10 to 11), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 15.3.6*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 10 to 11), for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 9), same as 00; channel x (x = 10 to 11), at 2D/repeated block level. The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 15.3.1 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 15.3.5* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 15.3.3*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[6:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **REQSEL[6:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 15.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[6:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

15.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 9)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

15.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 10 to 11)

Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is

automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.

– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.

- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

15.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

15.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

15.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 10 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

15.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 10 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

15.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 9)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0: no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

15.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 10 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

16 Nested vectored interrupt controller (NVIC)

16.1 NVIC main features

- 96 maskable interrupt channels (not including the 16 Cortex-M33 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late arriving interrupts.

The NVIC registers are banked across secure and nonsecure states. All interrupts including the core exceptions are managed by the NVIC. For more information about NVIC and its registers, refer to the *programming manual for Cortex-M33* (PM0223).

16.2 SysTick calibration value register

The Cortex-M33 with TrustZone mainline security extension embeds two SysTick timers. When TrustZone is activated, the following SysTick timers are available:

- SysTick, secure instance
- SysTick, nonsecure instance

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. In order to match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When SysTick clock source is CPU clock HCLK reload value = (HCLK x STCALIB) - 1
- When SysTick clock source is external clock (HCLK/8) reload value = ((HCLK/8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms: SysTick reload value = (100 x STCALIB) - 1 = 0x1869F

For more information about SysTick and its registers, refer to the *programming manual for Cortex-M33* (PM0223).

16.3 Interrupt and exception vectors

The grey rows in the table below indicate core exceptions.

Table 128. STM32U3 series vector table(1)

IRQ number	Priority(2)	Acronym	Description	Address offset
-	-4	Reset	Reset	0x0000 0004

Table 128. STM32U3 series vector table(1) (continued)

IRQ number	Priority(2)	Acronym	Description	Address offset
123	Settable	PWR	PWR nonsecure interrupt	0x0000 022C
124	Settable	PWR_S	PWR secure interrupt	0x0000 0230

1. Some interrupt lines are only available on some STM32U3 series devices. Refer to the device datasheet for availability of associated peripheral. If not present, consider this interrupt line as reserved.
2. If multiple pending interrupts have the same programmed priority level, the pending interrupt with the lowest IRQ number takes precedence. For example, if both interrupt[n] and interrupt[n+1] are pending and have the same priority, then interrupt[n] is processed before interrupt[n+1]. For further information, refer to the Arm Cortex-M33 technical documentation.

17 Extended interrupts and event controller (EXTI)

17.1 EXTI introduction

The extended interrupts and event controller (EXTI) manages the individual CPU and system wake-up through configurable event inputs. It provides wake-up requests to the power control and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wake-up requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes. The EXTI also includes the EXTI mux I/O port selection.

17.2 EXTI main features

The EXTI main features are the following:

- Up to 23 input events supported
- All event inputs allow the possibility to wake up the system
- Events that do not have an associated wake-up flag in the peripheral, have a flag in the EXTI and generate an interrupt to the CPU from the EXTI
- Events can be used to generate a CPU wake-up event
- Secure events: The access to control and configuration bits of secure input events can be made secure
- EXTI I/O port selection

The configurable events have the following features:

- Selectable active trigger edge
- Interrupt pending status register bits independent for the rising and falling edge
- Individual interrupt and event generation mask, used for conditioning the CPU wake-up, interrupt and event generation
- Software trigger possibility

17.3 EXTI functional description

17.3.1 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block and EXTI mux as shown in *Figure 61*.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wake-up, interrupt and event outputs, and their masking.

The EXTI mux provides the I/O port selection of the EXTI event signal.

Figure 61. EXTI block diagram

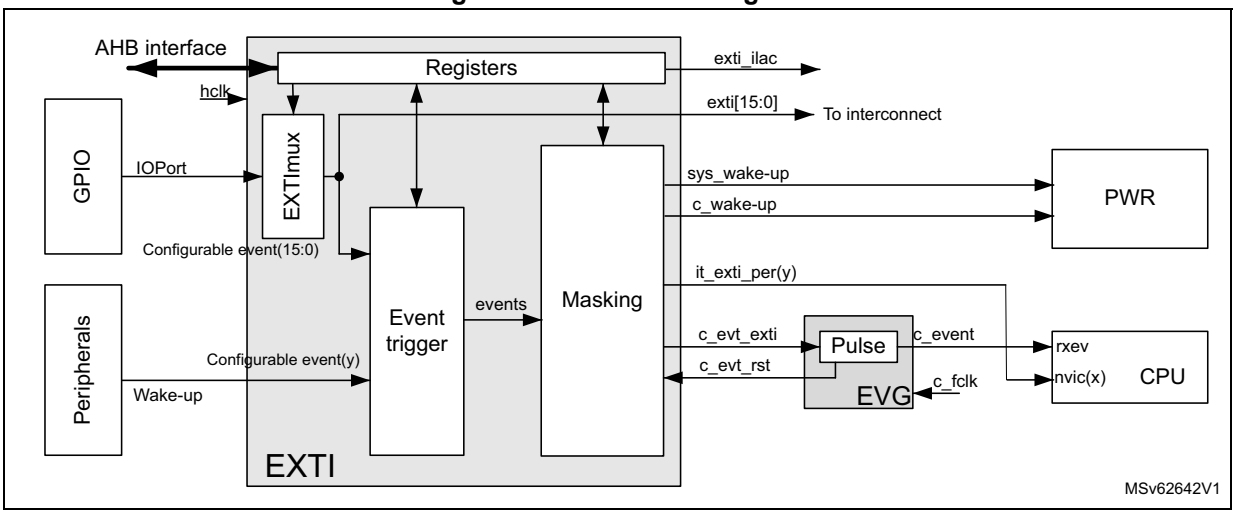

Table 129. EXTI signals

Name	I/O	Description
AHB interface	I/O	EXTI register bus interface. When one event is configured to enable security, the AHB interface supports secure accesses.
hclk	I	AHB bus clock and EXTI system clock
Configurable event(y)	I	Asynchronous wake-up events from peripherals that do not have an associated interrupt and flag in the peripheral
exti_ilac	O	Illegal access event
IOPort(n)	I	GPIOs block I/O ports[15:0]
exti[15:0]	O	EXTI GPIO output port to trigger other peripherals
it_exti_per (y)	O	Interrupts to the CPU associated with configurable event (y)
c_evt_exti	O	High-level sensitive event output for CPU, synchronous to hclk
c_evt_rst	I	Asynchronous reset input to clear c_evt_exti
sys_wakeup	O	Asynchronous system wake-up request to PWR for ck_sys and hclk
c_wakeup	O	Wake-up request to PWR for CPU, synchronous to hclk

Table 130. EVG signals

Name	I/O	Description
c_fclk	I	CPU free running clock
c_evt_in	I	High-level sensitive events input from EXTI, asynchronous to CPU clock
c_event	O	Event pulse, synchronous to CPU clock
c_evt_rst	O	Event reset signal, synchronous to CPU clock

EXTI connections between peripherals and CPU

Some peripherals able to generate wake-up or interrupt events when the system is in Stop mode, are connected to the EXTI.

- Peripheral wake-up signals that generate a pulse or do not have an interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit that requires to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wake-up signals are connected to the PWR and are used to wake up the system and the CPU sub- system bus clocks.

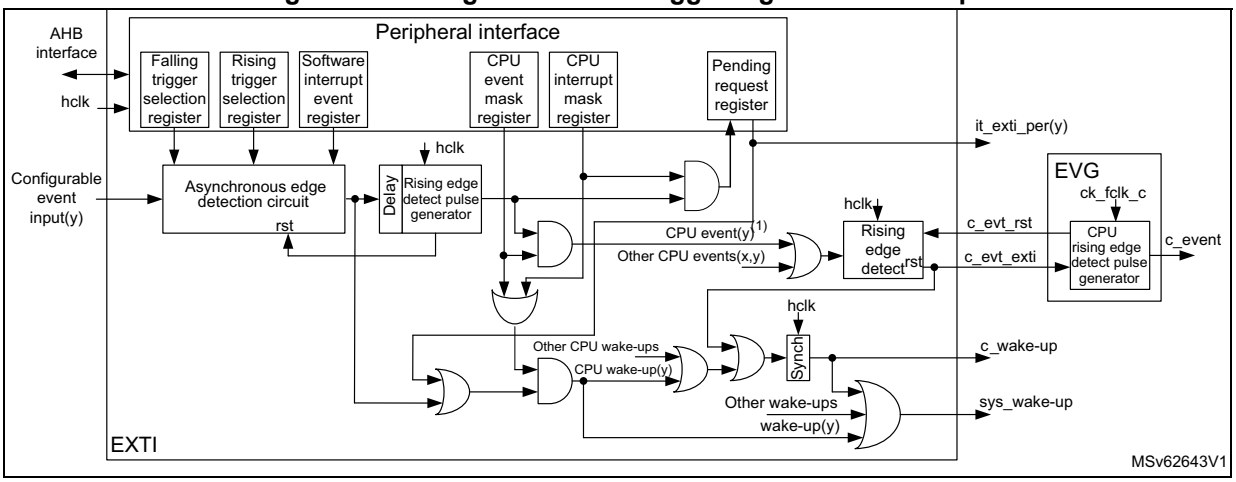
EXTI interrupt/event mapping

The EXTI lines are connected as shown in the table below.

Table 131. EXTI line connections

EXTI line	Line source	Line type
0-15	GPIO	Configurable
16	PVD output	Configurable
17	COMP1 output	Configurable
18	COMP2 output	Configurable
19	V_{DDUSB} voltage monitor	Configurable
20	V_{DDIO2} voltage monitor	Configurable
21	V_{DDA} voltage monitor 1	Configurable
22	V_{DDA} voltage monitor 2	Configurable

17.3.2 Event features control



The events features are controlled from register bits as follows:

- Active trigger edge enable by
  - rising edge selection in the *EXTI rising trigger selection register (EXTI_RTSR1)*
  - falling edge selection in the *EXTI falling trigger selection register (EXTI_FTSR1)*
- Software trigger in the *EXTI software interrupt event register (EXTI_SWIER1)*
- Interrupt pending flag in the
  - *EXTI rising edge pending register (EXTI_RPR1)*
  - *EXTI falling edge pending register (EXTI_FPR1)*
- CPU wake-up and interrupt enable in the
  - *EXTI CPU wake-up with interrupt mask register (EXTI_IMR1)*
- CPU wake-up and event enable
  - *EXTI CPU wake-up with event mask register (EXTI_EMR1)*

17.3.3 EXTI configurable event input wake-up

The figure below is a detailed representation of the logic associated with configurable event inputs that wake up the CPU sub-system bus clocks and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wake-up event.

Figure 62. Configurable event trigger logic CPU wake-up

1. Only for the input events that support CPU rxev generation c_event.

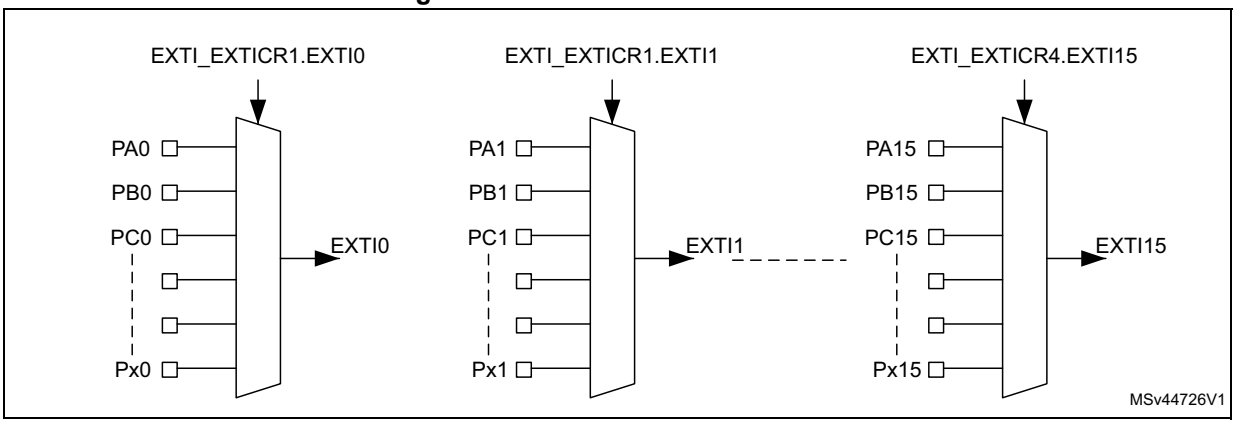
The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wake-up (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR1 and EXTI_FPR1) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR1 and/or EXTI_FPR1 registers.

When a CPU wake-up (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.



Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

17.3.4 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wake-up. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event.

The selection of GPIO port as EXTI mux output is controlled in the EXTI_EXTICRx.

Figure 63. EXTI mux GPIO selection

The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR1 and EXTI_EMR1 registers.

17.3.5 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the CPU wake-up generation is conditioned by the CPU interrupt mask and CPU event mask.

Table 132. Masking functionality

CPU interrupt enable (in EXTI_IMR.IMn)	CPU event enable (in EXTI_EMR.EMn)	Configurable event inputs (in EXTI_RPR.RPIFn and EXTI_FPR.FPIFn)	Exti(n) interrupt(1)	CPU event	CPU wake-up
0	0	No	Masked	Masked	Masked
	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes(2)
	1	Status latched	Yes	Yes	Yes

1. The single exti(n) interrupt goes to the CPU. If no interrupt is required for CPU(m), the exti(n) interrupt must be masked in the CPU NVIC.
2. 2.Only if CPU interrupt is enabled in EXTI_IMR1.IMn.

For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits EXTI_RPR1.RPIFn and/or EXTI_FPR1.FPIFn is/are set: the CPU sub-system is woken up and the CPU interrupt signal is activated. The EXTI_RPR1.RPIFn and/or EXTI_FPR1.FPIFn pending bits must be cleared by software writing it to 1. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER1, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR1, whatever the setting in EXTI_RTSR1.

17.3.6 EXTI event protection

The EXTI is able to protect event register bits from being modified by nonsecure and unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_SECCFGR1 and EXTI_PRIVCFGR1. At EXTI level, the protection consists in preventing the following unauthorized write access:

- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

Table 133. Register protection overview

Register name	Access type	Protection(1)(2)
EXTI_RTSR1	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR1 and EXTI_PRIVCFGR1.
EXTI_FTSR1	RW	
EXTI_SWIER1	RW	
EXTI_RPR1	RW	
EXTI_FPR1	RW	
EXTI_SECCFGR1	RW	Always secure. Privilege can be bit-wise enabled in EXTI_PRIVCFGR1.
EXTI_PRIVCFGR1	RW	Always privilege. Security can be bit-wise enabled in EXTI_SECCFGR1.
EXTI_EXTICRx	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR1 and EXTI_PRIVCFGR1.
EXTI_LOCKR	RW	Always secure.
EXTI_IMR1	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR1 and EXTI_PRIVCFGR1.
EXTI_EMR1	RW	

1. Privilege is enabled with the individual Input event (EXTI_PRIVCFGR1 register).
2. Security is enabled with the individual input event (EXTI_SECCFGR1 register).

EXTI security protection

When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access. A nonsecure write access is discarded and a read returns 0.

When input events are nonsecure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and nonsecure access.

The security configuration in EXTI_SECCFGR1 can be globally locked after reset by EXTI_LOCKR.LOCK.

EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

The privileged configuration in EXTI_PRIVCFGR1 can be globally locked after reset by EXTI_LOCKR.LOCK.

17.4 EXTI registers

All registers can be accessed with word (32-bit), half-word (16-bit), and byte (8-bit) access.

17.4.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT22	RT21	RT20	RT19	RT18	RT17	RT16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RT15	RT14	RT13	RT12	RT11	RT10	RT9	RT8	RT7	RT6	RT5	RT4	RT3	RT2	RT1	RT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **RTi:** Rising trigger event configuration bit of configurable event input i[(1)] (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, RTx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECi is enabled, RTi can only be accessed with secure access. Nonsecure write to this bit i is discarded and nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVi is disabled, RTi can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVi is enabled, RTi can only be accessed with privileged access. Unprivileged write to this bit i is discarded. Unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered. No glitch must be generated on these inputs. If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

17.4.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT22	FT21	FT20	FT19	FT18	FT17	FT16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FT15	FT14	FT13	FT12	FT11	FT10	FT9	FT8	FT7	FT6	FT5	FT4	FT3	FT2	FT1	FT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **FTi:** Falling trigger event configuration bit of configurable event input i[(1)] (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, FTi can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECi is enabled, FTi can only be accessed with secure access. Nonsecure write to this FTi is discarded. Nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVi is disabled, FTi can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVi is enabled, FTi can only be accessed with privileged access. Unprivileged write to this FTi is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and interrupt) for input line

1: Falling trigger enabled (for event and interrupt) for input line.

1. The configurable event inputs are edge triggered. No glitch must be generated on these inputs. If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

17.4.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI22	SWI21	SWI20	SWI19	SWI18	SWI17	SWI16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWI15	SWI14	SWI13	SWI12	SWI11	SWI10	SWI9	SWI8	SWI7	SWI6	SWI5	SWI4	SWI3	SWI2	SWI1	SWI0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **SWIi:** Software interrupt on event i (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, SWIi can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECi is enabled, SWIi can only be accessed with secure access. Nonsecure write to this SWIi is discarded. Nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVi is disabled, SWIi can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVi is enabled, SWIi can only be accessed with privileged access. Unprivileged write to this SWIi is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event i. This bit is auto cleared by hardware.

17.4.4 EXTI rising edge pending register (EXTI_RPR1)

Address offset: 0x00C

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF22	RPIF21	RPIF20	RPIF19	RPIF18	RPIF17	RPIF16
									rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RPIF15	RPIF14	RPIF13	RPIF12	RPIF11	RPIF10	RPIF9	RPIF8	RPIF7	RPIF6	RPIF5	RPIF4	RPIF3	RPIF2	RPIF1	RPIF0
rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **RPIFi:** Configurable event input i rising edge pending bit (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, RPIFi can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECi is enabled, RPIFi can only be accessed with secure access. Nonsecure write to this RPIFi is discarded. Nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVi is disabled, RPIFi can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVi is enabled, RPIFi can only be accessed with privileged access. Unprivileged write to this RPIFi is discarded, unprivileged read returns 0.

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

0: No rising edge trigger request occurred.

1: Rising edge trigger request occurred.

17.4.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF22	FPIF21	FPIF20	FPIF19	FPIF18	FPIF17	FPIF16
									rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FPIF15	FPIF14	FPIF13	FPIF12	FPIF11	FPIF10	FPIF9	FPIF8	FPIF7	FPIF6	FPIF5	FPIF4	FPIF3	FPIF2	FPIF1	FPIF0
rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **FPIFi:** configurable event inputs i falling edge pending bit (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, FPIFi can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECi is enabled, FPIFi can only be accessed with secure access. Nonsecure write to this FPIFi is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVi is disabled, FPIFi can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVi is enabled, FPIFi can only be accessed with privileged access. Unprivileged write to this FPIFi is discarded, unprivileged read returns 0.
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred

17.4.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014

Reset value: 0x0000 0000

This register provides write access security. A nonsecure write access is ignored and causes the generation of an illegal access event. A nonsecure read returns the register data. This register contains only bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC22	SEC21	SEC20	SEC19	SEC18	SEC17	SEC16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **SECi:** Security enable on event input i (i = 22 to 0)
When EXTI_PRIVCFGR.PRIVi is disabled, SECi can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVi is enabled, SECi can only be written with privileged access. Unprivileged write to this SECi is discarded.
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

17.4.7 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data. This register contains only bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV22	PRIV21	PRIV20	PRIV19	PRIV18	PRIV17	PRIV16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRIV15	PRIV14	PRIV13	PRIV12	PRIV11	PRIV10	PRIV9	PRIV8	PRIV7	PRIV6	PRIV5	PRIV4	PRIV3	PRIV2	PRIV1	PRIV0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **PRIVi:** Security enable on event input i (i = 22 to 0)
When EXTI_SECCFGR.SECi is disabled, PRIVi can be accessed with secure and nonsecure access.
When EXTI_SECCFGR.SECi is enabled, PRIVi can only be written with secure access. Nonsecure write to this PRIVi is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

17.4.8 EXTI external interrupt selection register (EXTI_EXTICRx)

Address offset: 0x060 + 0x4 * (x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EXTI{4*(x-1)+3}[7:0]								EXTI{4*(x-1)+2}[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI{4*(x-1)+1}[7:0]								EXTI{4*(x-1)}[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **EXTI{4 * (x - 1) + 3}[7:0]:** EXTI{4 * (x - 1) + 3} GPIO port selection

These bits are written by software to select the source input for EXTI{4 * (x - 1) + 3} external interrupt.

When EXTI_SECCFGR.SEC{4 * (x - 1) + 3} is disabled, this bitfield can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SEC{4 * (x - 1) + 3} is enabled, this bitfield can only be accessed with secure access. Nonsecure write is discarded. Nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIV{4 * (x - 1) + 3} is disabled, this bitfield can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIV{4 * (x - 1) + 3} is enabled, this bitfield can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0x00: PA[{4 * (x - 1) + 3}] pin
0x01: PB[{4 * (x - 1) + 3}] pin

17.4.9 EXTI lock register (EXTI_LOCKR)

Address offset: 0x070

Reset value: 0x0000 0000

This register provides write access security: a nonsecure write access is ignored, a read access returns zero data, and both generates an illegal access event.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LOCK**: Global security and privilege configuration registers (EXTI_SECCFGR and EXTI_PRIVCFGR) lock

This bit is written once after reset.

0: Security and privilege configuration open, can be modified.

1: Security and privilege configuration locked, can no longer be modified.

17.4.10 EXTI CPU wake-up with interrupt mask register (EXTI_IMR1)

Address offset: 0x080

Reset value: 0x0000 0000

This register contains bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IM22	IM21	IM20	IM19	IM18	IM17	IM16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **IMi:** CPU wake-up with interrupt mask on event input i[(1)] (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, IMi can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECi is enabled, IMi can only be accessed with secure access. Nonsecure write to this bit is discarded. Nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVi is disabled, IMi can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVi is enabled, IMi can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wake-up with interrupt request from input event i is masked.

1: Wake-up with interrupt request from input event i is unmasked.

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

17.4.11 EXTI CPU wake-up with event mask register (EXTI_EMR1)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EM22	EM21	EM20	EM19	EM18	EM17	EM16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **EMi:** CPU wake-up with event generation mask on event input i (i = 22 to 0)

When EXTI_SECCFGR.SECi is disabled, EMi can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECi is enabled, EMi can only be accessed with secure access. Nonsecure write to this EMi is discarded. Nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVi is disabled, EMi can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVi is enabled, EMi can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wake-up with event generation from line i is masked.

1: Wake-up with event generation from line i is unmasked.

17.4.12 EXTI register map

Table 134. EXTI register map and reset values

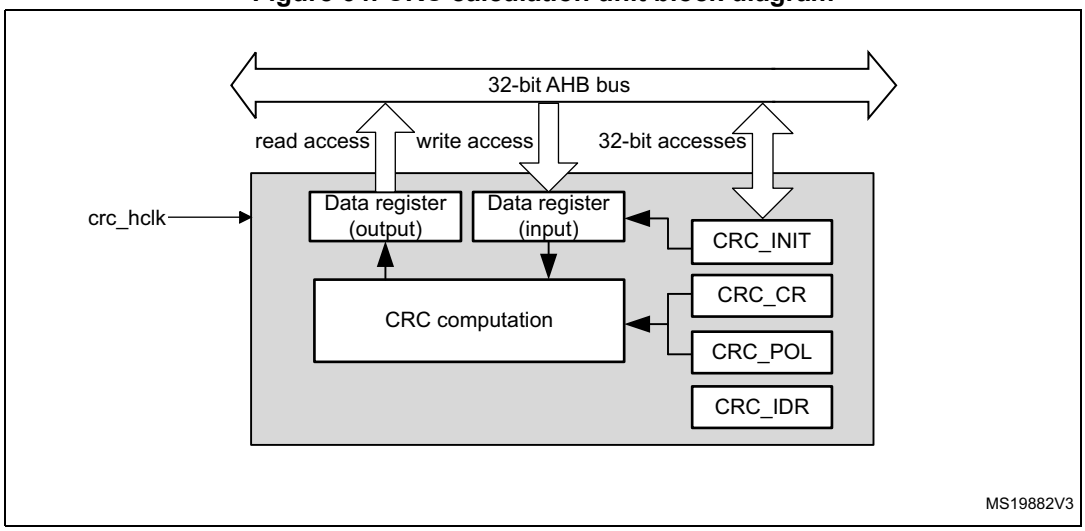
Refer to *Section 2.3* for the register boundary addresses.

18 Cyclic redundancy check calculation unit (CRC)

18.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.



18.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility options on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

18.3 CRC functional description

18.3.1 CRC block diagram

Figure 64. CRC calculation unit block diagram

18.3.2 CRC internal signals

Table 135. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

18.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. When the RTYPE_IN bit is set in CRC_CR, non-word accesses to CRC_DR register are ignored. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register. If RTYPE_IN bit is set in this register, the input reversing operation can be performed with a byte or half-word granularity, but not with single bit granularity.

For example, with RTYPE_IN cleared, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte (REV_IN[1:0] = 01)
- 0xD458B23C with bit-reversal done by half-word (REV_IN[1:0] = 10)
- 0xB23CD458 with bit-reversal done on the full word (REV_IN[1:0] = 11)

With RTYPE_IN set, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x3C4D1A2B with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x4D3C2B1A with byte-reversal done by word (REV_IN[1:0] = 10)

The output data can also be reversed by setting the REV_OUT[1:0] bits in the CRC_CR register. If RTYPE_OUT is set in this register, the output reversing operation is performed with a byte or half-word granularity, but not with single bit granularity.

With RTYPE_OUT cleared, the operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

With RTYPE_OUT set, 0x11223344 output data are converted as:

- 0x33441122 with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x44332211 with byte-reversal done by word (REV_IN[1:0] = 10)

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

18.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes when RTYPE bit is cleared in CRC_CR. When RTYPE is set, only word accesses are allowed. For the other registers only 32-bit accesses are allowed.

18.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

18.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

18.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	RTYPE_OUT	RTYPE_IN	REV_OUT[1:0]		REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
					rw	rw	rw	rw	rw	rw	rw	rw			rs

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **RTYPE_OUT**: Reverse type output
This bit controls the reversal granularity of the output data.
0: Bit level output
1: Byte or half-word level output

Bit 9 **RTYPE_IN**: Reverse type input
This bit controls the reversal granularity of the input data.
0: Bit level input
1: Byte or half-word level input

Bits 8:7 **REV_OUT[1:0]**: Reverse output data
This bitfield controls the reversal of the bit order of the output data.
00: Bit order not affected (RTYPE_OUT = 0 or 1)
01: Bit-reversed output format (RTYPE_OUT = 0) or half-word reversal done by word (RTYPE_OUT = 1)
10: Bit order not affected (RTYPE_OUT = 0) or byte reversal done by word (RTYPE_OUT = 1)
11: Bit order not affected (RTYPE_OUT = 0 or 1)

Bits 6:5 **REV_IN[1:0]**: Reverse input data
This bitfield controls the reversal of the bit order of the input data
00: Bit order not affected (RTYPE_IN = 0 or 1)
01: Bit reversal done by byte (RTYPE_IN = 0) or half-word reversal done by word (RTYPE_IN = 1)
10: Bit reversal done by half-word (RTYPE_IN = 0) or byte reversal done by word (RTYPE_IN = 1)
11: Bit reversal done by word (RTYPE_IN = 0) or bit order is not affected (RTYPE_IN = 1)

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size
These bits control the size of the polynomial.
00: 32 bit polynomial
01: 16 bit polynomial
10: 8 bit polynomial
11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit
This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware

18.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value
This register is used to write the CRC initial value.

18.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial
This register is used to write the coefficients of the polynomial to be used for CRC calculation.
If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

18.4.6 CRC register map

Table 136. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

19 Extended-SPI interface (OCTOSPI)

19.1 OCTOSPI introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

19.2 OCTOSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, and octal communication
- Dual memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

19.3 OCTOSPI implementation

19.4.2 OCTOSPI pins and internal signals

Table 138. OCTOSPI input/output pins

Pin name	Type	Description
OCTOSPI_NCLK	Output	OCTOSPI inverted clock to support 1.8 V HyperBus protocol
OCTOSPI_CLK		OCTOSPI clock
OCTOSPI_IOn (n = 0 to 7)	Input/output	OCTOSPI data pins
OCTOSPI_NCS	Output	Chip select for the memory
OCTOSPI_DQS	Input/output	Data strobe/write mask signal from/to the memory

Caution: Use the same configuration (output speed, HSLV[(a)]) for all OCTOSPI input/output pins to avoid any data corruption.

Table 139. OCTOSPI internal signals

Signal name	Type	Description
octospi_hclk	Input	OCTOSPI AHB clock
octospi_ker_ck	Input	OCTOSPI kernel clock
octospi_dma	N/A	DMA request signal
octospi_it	Output	Global interrupt line (see *Table 143* for the multiple sources of interrupt)

a. When applicable.

19.4.3 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:

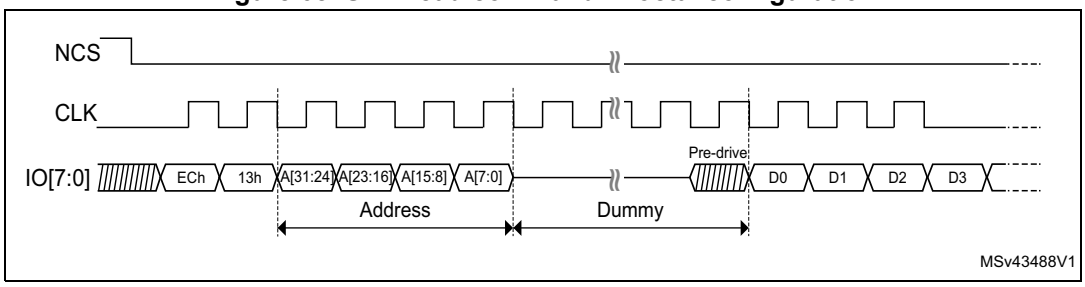
- regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

19.4.4 OCTOSPI regular-command protocol

When in regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:



- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 68. SDR read command in octal configuration

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR, and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in OCTOSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in OCTOSPI_AR. In memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

Alternate-byte phase

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR, and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-SPI, the quad-SPI, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR, and the data received from the external device can be obtained by reading OCTOSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

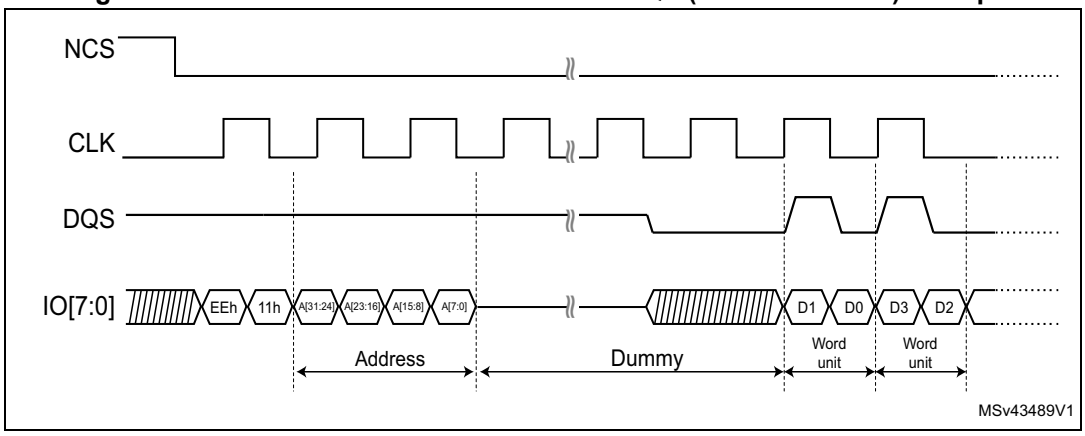
The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.



In memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in OCTOSPI_CCR.

Figure 69. DTR read in octal-SPI mode with DQS (Macronix mode) example

19.4.5 OCTOSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the OCTOSPI generating the clock.

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

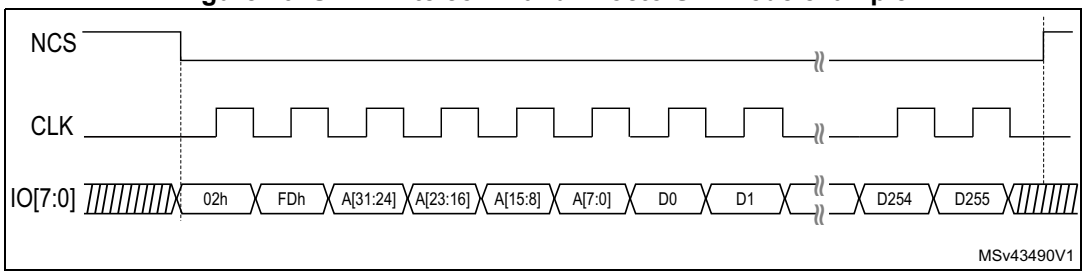
Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.



Single-data rate (SDR) mode

By default, all the phases operate in SDR mode.

In this mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

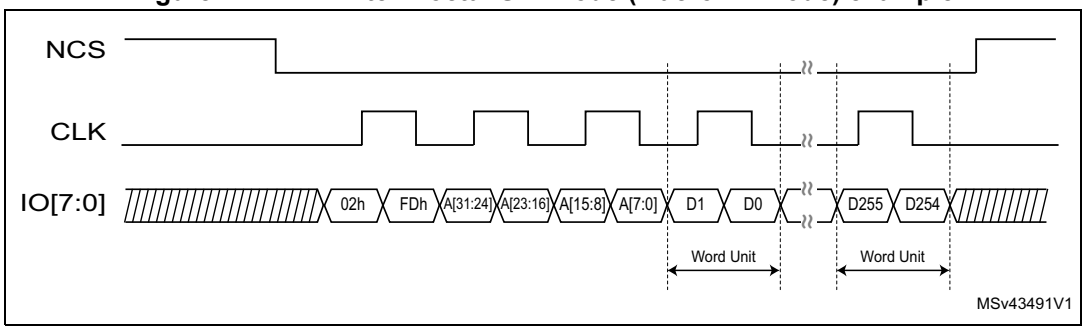
Figure 70. SDR write command in octo-SPI mode example

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.



In DTR mode, when the OCTOSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 71. DTR write in octal-SPI mode (Macronix mode) example

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 011, two external Quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in OCTOSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

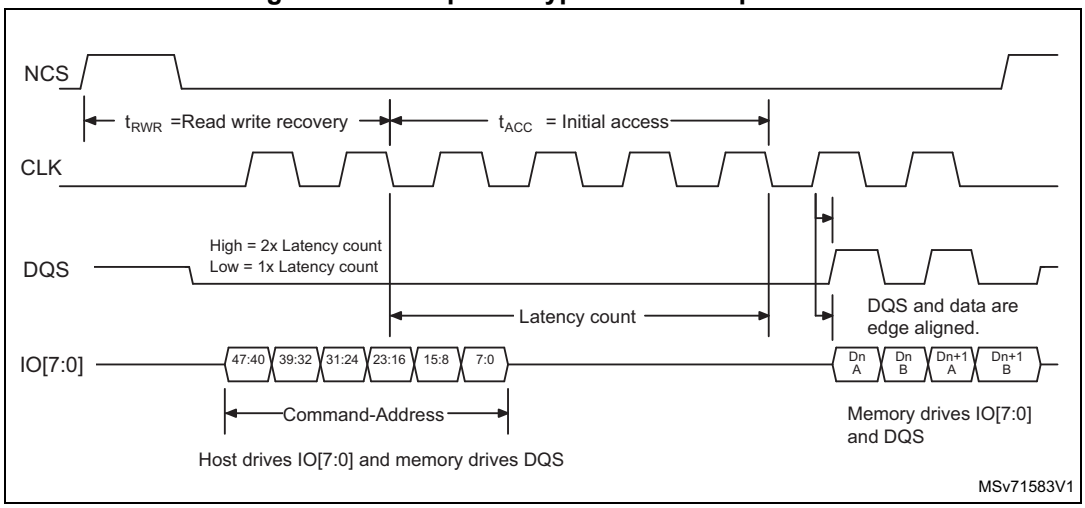
Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

19.4.6 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- DQS for read and write data strobe and latency insertion
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)



The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 72. Example of HyperBus read operation

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 140. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

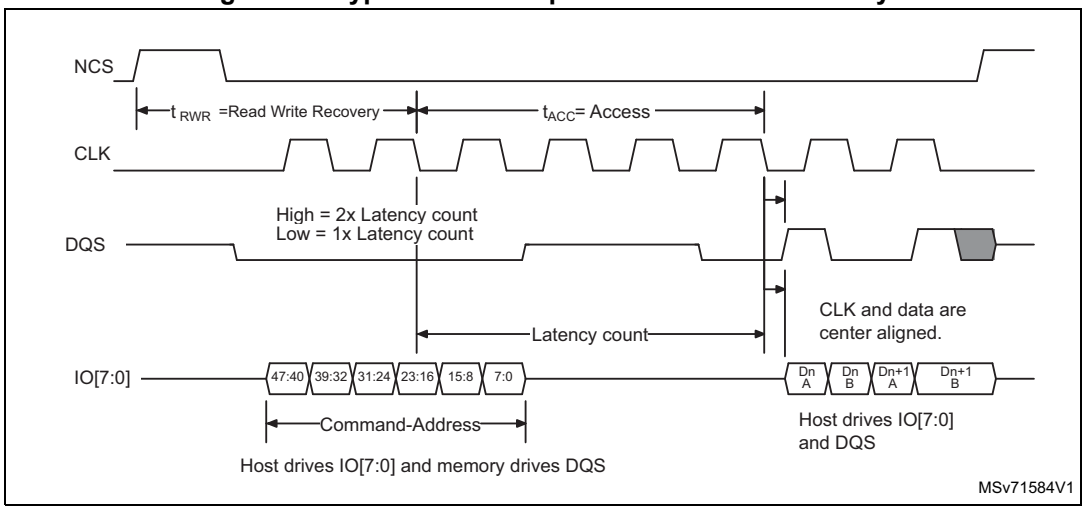
The address space is configured through the memory type MTYP[2:0] in OCTOSPI_DCR1.

The total size of the device must be configured through DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in OCTOSPI_HLCR)
- t_{ACC}: access time for the device (defined by TACC[7:0] in OCTOSPI_HLCR) according to the memory latency



During the read operation, the DQS is used by the device, in two ways (see *Figure 72*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

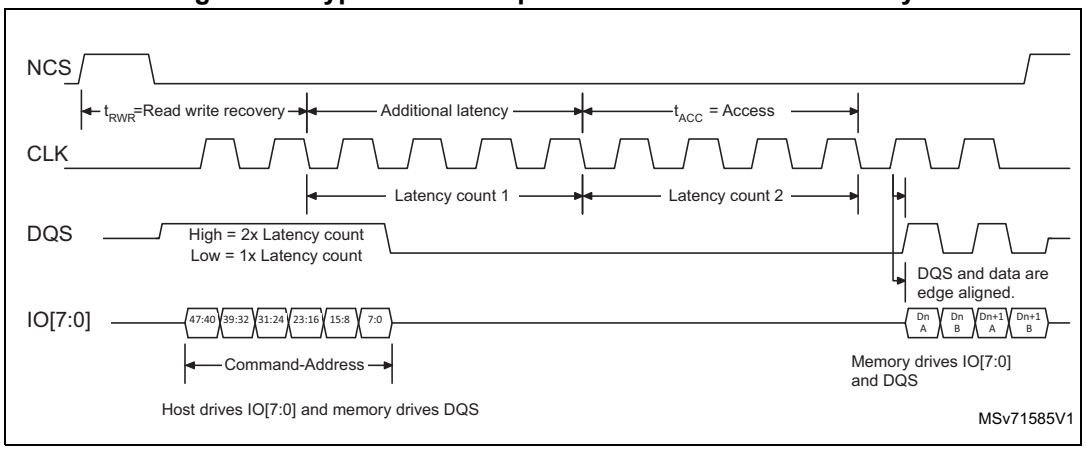
Figure 73. HyperBus write operation with initial latency

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the OCTOSPI to meet the device request.

Figure 74. HyperBus read operation with additional latency



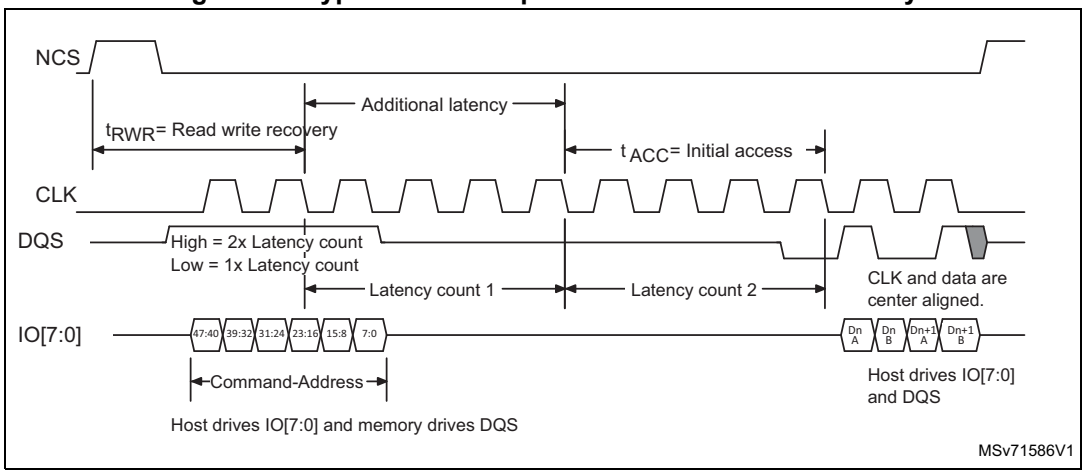


Figure 75. HyperBus write operation with additional latency

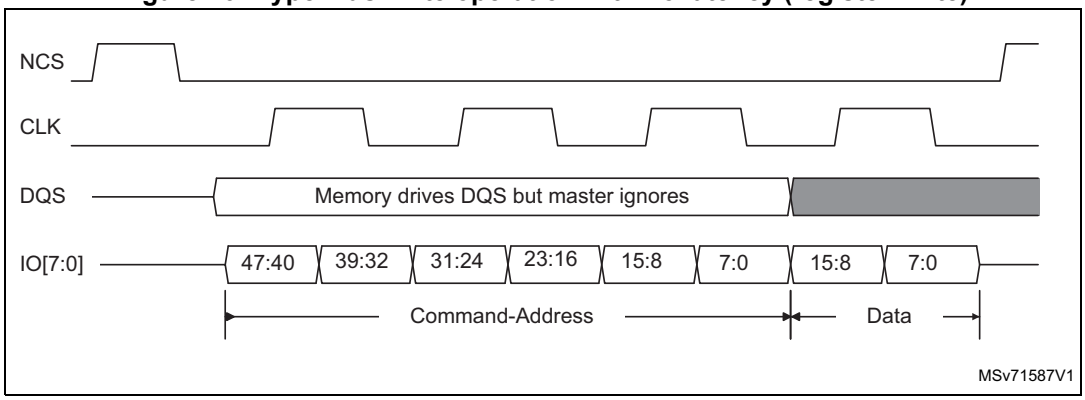
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.



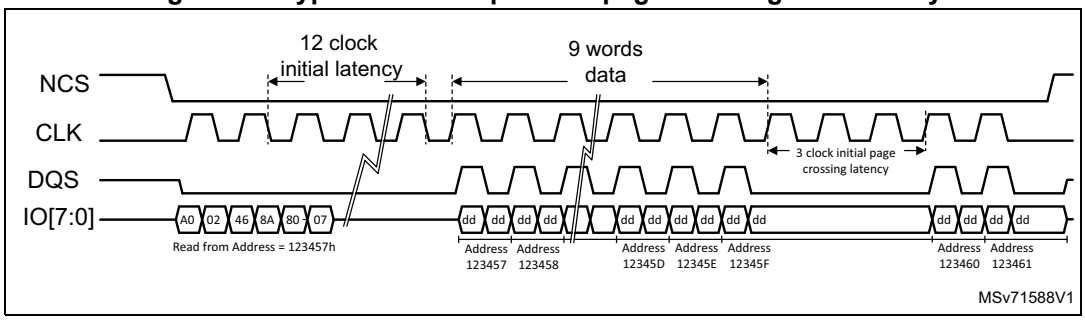
The latency can be forced to 2 x t_{ACC} by setting LM in OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the DQS signal is not taken into account by the OCTOSPI, and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

Figure 76. HyperBus write operation with no latency (register write)



Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 77. HyperBus read operation page crossing with latency

19.4.7 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh

Wrap support

The OCTOSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated OCTOSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (OCTOSPI_CCR, OCTOSPI_TCR, OCTOSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in OCTOSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, reissues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

19.4.8 OCTOSPI operating mode introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

19.4.9 OCTOSPI indirect mode

In indirect mode, the commands are started by writing to the OCTOSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in OCTOSPI_CR, the OCTOSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading OCTOSPI_DR.

In indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as

defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.

- If DL[31:0] = 0xFFFF FFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in OCTOSPI_SR, and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR, and immediately transferred in the internal FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

19.4.10 OCTOSPI automatic status-polling mode

In automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. The memory must then be configured in fixed latency.

19.4.11 OCTOSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the OCTOSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be

programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.

- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

19.4.12 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

19.4.13 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

19.4.14 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the clock mode with FRCK and CKMODE
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{\text{DEVSIZE+1}}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

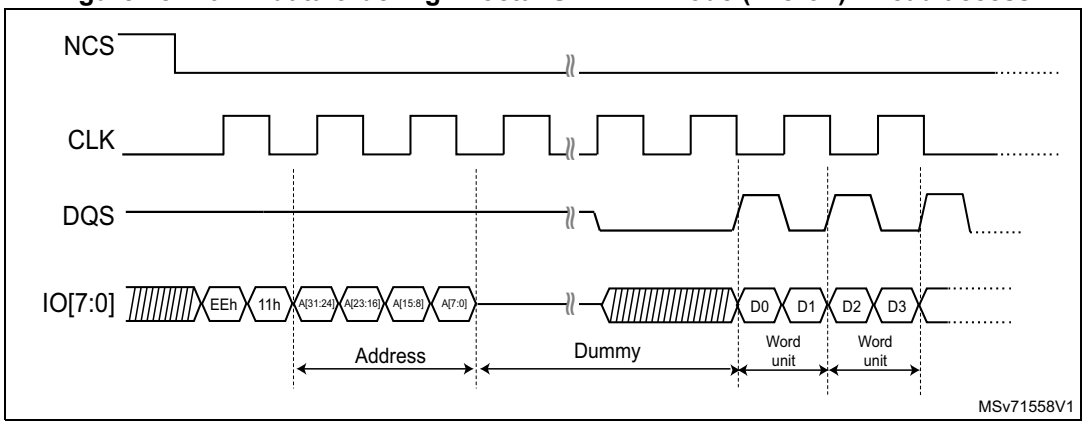
If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in OCTOSPI_HLCR.



Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the OCTOSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:

- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 78. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the

memory. Refer to *Figure 69: DTR read in octal-SPI mode with DQS (Macronix mode) example*.

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 141: OctaRAM command address bit assignment (based on 64-Mbyte OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock one when reading data from the memory.

Figure 79. OctaRAM read operation with reverse data ordering D1/D0

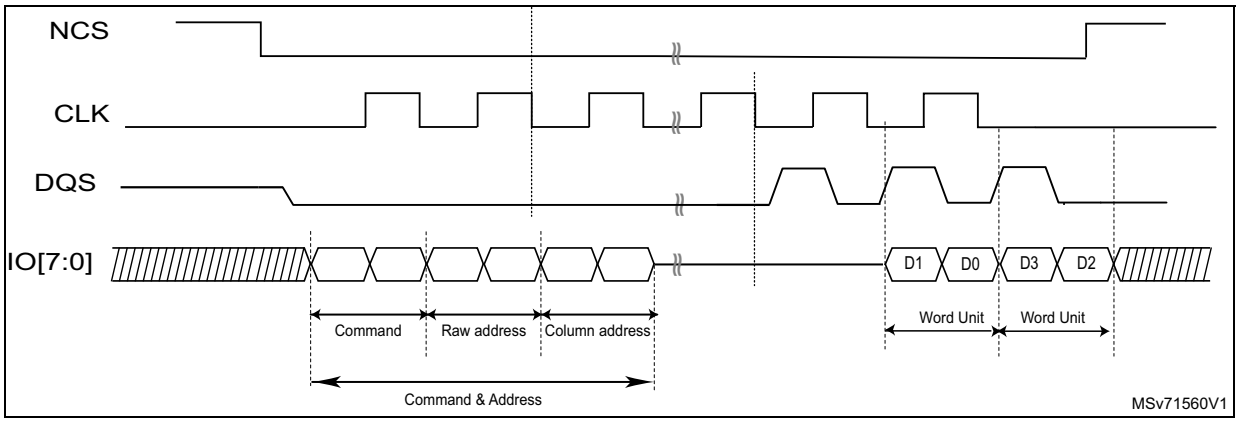


Table 141. OctaRAM command address bit assignment (based on 64-Mbyte(1) OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0(2)

1. Example of 64-Mbyte OctaRAM address assignment:
   Row Address [RA12:RA0]: 8K. Column address [CA9:CA0]: 1K. 64-Mbyte density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes

must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.

- Standard mode. It is the mode to use whenever the targeted memory is not corresponding to any others configurations described in this section. MTYP[2:0] = 010 for this standard mode.

19.4.15 OCTOSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000),
the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

When the OCTOSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.

7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

OCTOSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

OCTOSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

Sending the instruction only once (SIOO)

A flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

The SIOO mode is not supported when any of the communication regulations, NCS boundary, or refresh features are used.

19.4.16 OCTOSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

19.4.17 OCTOSPI error management

The following errors set the TEF flag in OCTOSPI_SR and generates an interrupt if enabled (TEIE = 1 in OCTOSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]).
- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.

In memory-mapped mode, the OCTOSPI generates an AHB slave error in the following situations,:

- The memory-mapped mode is disabled and an AHB read or write request occurs.
- A read or write address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing.
- The OCTOSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in OCTOSPI_WCCR in octal DTR mode, in dual-memory configuration, in HyperBus mode.

- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the AHB bus transfer size (HSIZE) is different from 4 bytes (only for memory-mapped mode).
- Bit DMM is set in OCTOSPI_CR (dual-memory configuration) and octal mode is set.

19.4.18 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

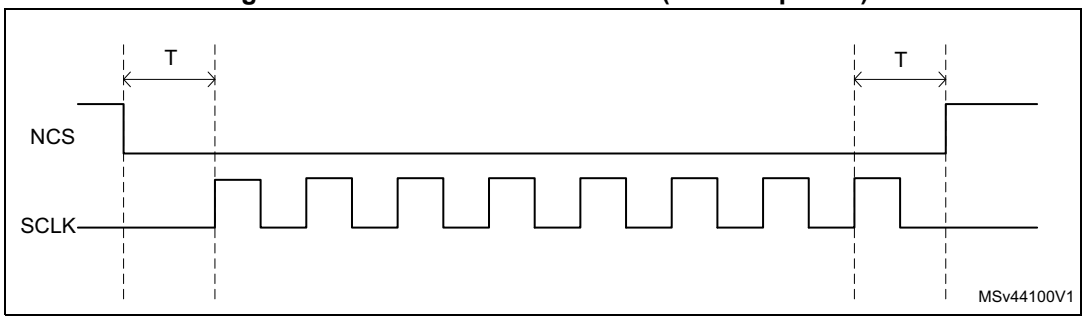
Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in OCTOSPI_DR, it is recommended to disable the DMA channel before aborting the OCTOSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

19.4.19 OCTOSPI reconfiguration or deactivation

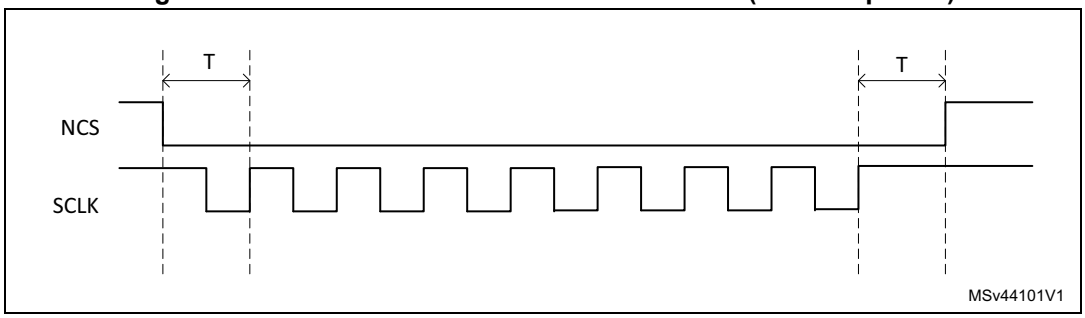
Before any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:



- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

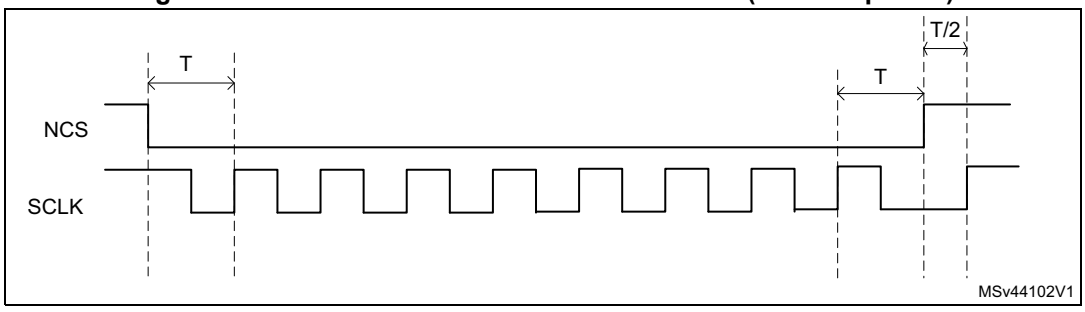
19.4.20 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.



When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 80. NCS when CKMODE = 0 (T = CLK period)



When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 81. NCS when CKMODE = 1 in SDR mode (T = CLK period)

When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

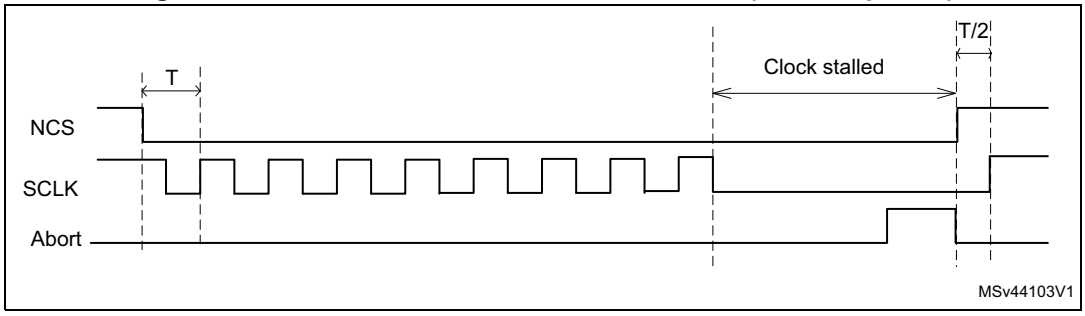


Figure 82. NCS when CKMODE = 1 in DTR mode (T = CLK period)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an

abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 83. NCS when CKMODE = 1 with an abort (T = CLK period)

19.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 142. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.

Table 142. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

19.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 143. OCTOSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

19.7 OCTOSPI registers

19.7.1 OCTOSPI control register (OCTOSPI_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	FMODE[1:0]		Res.	Res.	Res.	Res.	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
		rw	rw					rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					MSEL	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the OCTOSPI functional mode of operation.
00: Indirect-write mode
01: Indirect-read mode
10: Automatic status-polling mode (relevant in regular-command protocol only)
11: Memory-mapped mode
If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the automatic status-polling mode.
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop

This bit determines if the automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
1: Automatic status-polling mode stops as soon as there is a match.

Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable

This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable
This bit enables the status-match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level
This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI_SR, to be set.
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.
...
11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.
Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 **MSEL**: External memory select
This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).
0: External memory 1 selected (data exchanged over IO[3:0])
1: External memory 2 selected (data exchanged over IO[7:4])
This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Bit 6 **DMM**: Dual-memory configuration
This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity
0: Dual-memory configuration disabled
1: Dual-memory configuration enabled
Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the OCTOSPI.

0: OCTOSPI disabled

1: OCTOSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

19.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	Res.	DEVSIZE[4:0]

Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	DLY BYP	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw					rw		rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect-read/write modes must be used.

Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:

Number of bytes in device = $2^{[DEVSIZE+1]}$.

DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

In regular-command protocol, if DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...

0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set. Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).

0: CLK must stay low while NCS is high (chip-select released). This is referred to as clock mode 0.

1: CLK must stay high while NCS is high (chip-select released). This is referred to as clock mode 3.

19.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

19.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:0 Reserved, must be kept at reset value.

19.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled

Others: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the divided clock period: if OCTOSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

19.7.6 OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR).

It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.

It is cleared automatically as soon as the threshold condition is no longer true.

In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

19.7.7 OCTOSPI flag clear register (OCTOSPI_FCR)

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag
Writing 1 clears the TOF flag in the OCTOSPI_SR register.

Bit 3 **CSMF**: Clear status match flag
Writing 1 clears the SMF flag in the OCTOSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag
Writing 1 clears the TCF flag in the OCTOSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag
Writing 1 clears the TEF flag in the OCTOSPI_SR register.

19.7.8 OCTOSPI data length register (OCTOSPI_DLR)

Address offset: 0x0040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

19.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

19.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

19.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

19.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match
Value to be compared with the masked status register to get a match

19.7.13 OCTOSPI polling interval register (OCTOSPI_PIR)

Address offset: 0x0090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval
Number of CLK cycles between a read during the automatic status-polling phases

19.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR)

Address offset: 0x0100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SIOO	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]

Bit 31 **SIOO**: Send instruction only once mode
This bit has no effect when IMODE = 00 (see *Sending the instruction only once (SIOO)*).
0: Send instruction on every transaction
1: Send instruction only for the first command

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate- byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

19.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw		rw												

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle

0: No delay hold
1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
It is recommended to have at least six dummy cycles when using memories with DQS activated.

19.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

19.7.17 OCTOSPI alternate bytes register (OCTOSPI_ABR)

Address offset: 0x0120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address.

19.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR)

Address offset: 0x00130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period
After each access in memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.
This bitfield indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

19.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

19.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR)

Address offset: 0x0148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle

Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

19.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

19.7.23 OCTOSPI write communication configuration register (OCTOSPI_WCCR)

Address offset: 0x0180

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate-bytes phase.
0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

19.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR)

Address offset: 0x0188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.
0: Variable initial latency
1: Fixed latency

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

20 Secure digital input/output MultiMediaCard interface (SDMMC)

20.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (*e*•MMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and *e*•MMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

- Compliance with *Embedded MultiMediaCard System Specification Version 5.1*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit. (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)(HS400 is not supported).
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with *SD memory card specifications version 6.0*. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with *SDIO card specification version 4.0.* Card support for two different databus modes: 1-bit (default) and 4-bit. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode. (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.
- IDMA linked list support

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/*e*•MMC card at any one time and a stack of *e*•MMC.

20.2 SDMMC implementation

Table 145. SDMMC features

SDMMC modes/features(1)	SDMMC1
Variable delay (SDR104, HS200)	X
SDMMC_CKIN	X
SDMMC_CDIR, SDMMC_D0DIR	X
SDMMC_D123DIR	X

1. X = supported.

20.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

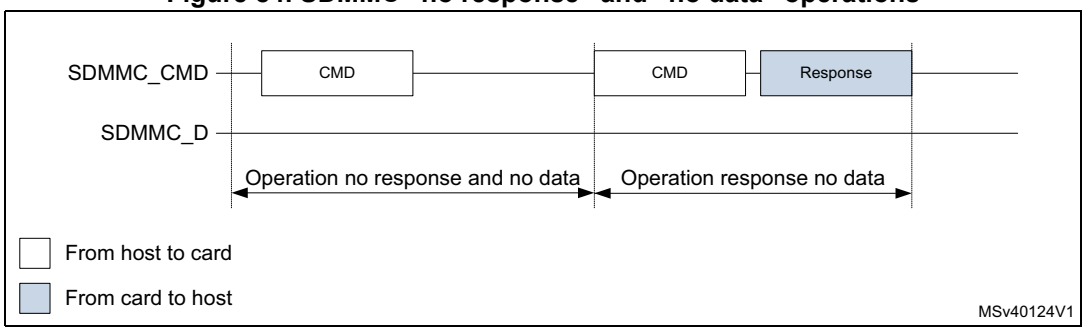
The basic transaction on the SD/SDIO/*e*•MMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

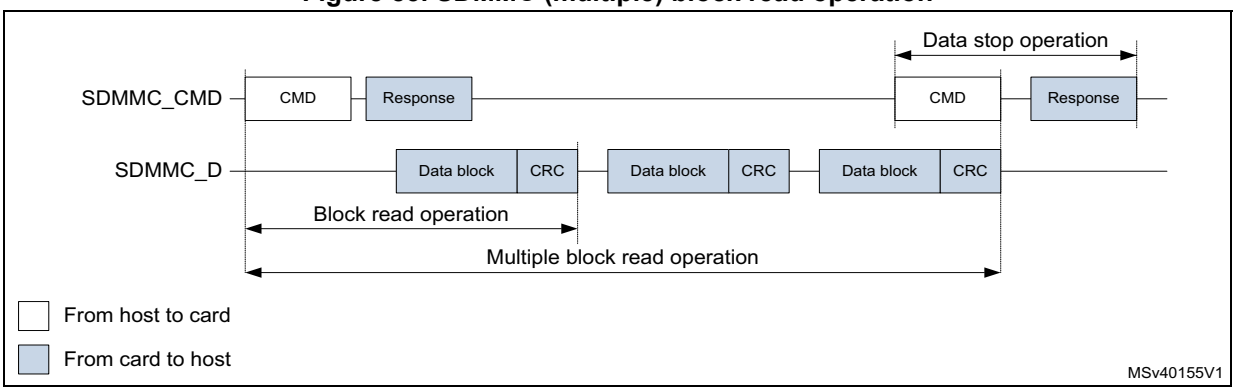
Data transfers are done in the following ways:

- Block mode: data block(s) with block size 2^N bytes with N in the range 0-14
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- *e*•MMC Stream mode: continuous data stream

Data transfers to/from *e*•MMC cards are done in data blocks or streams.

Figure 84. SDMMC "no response" and "no data" operations





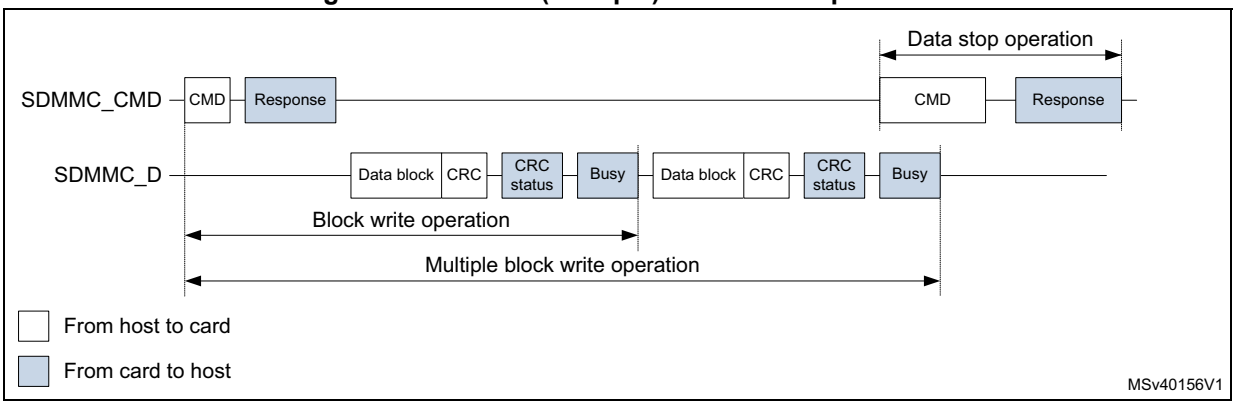


Figure 85. SDMMC (multiple) block read operation

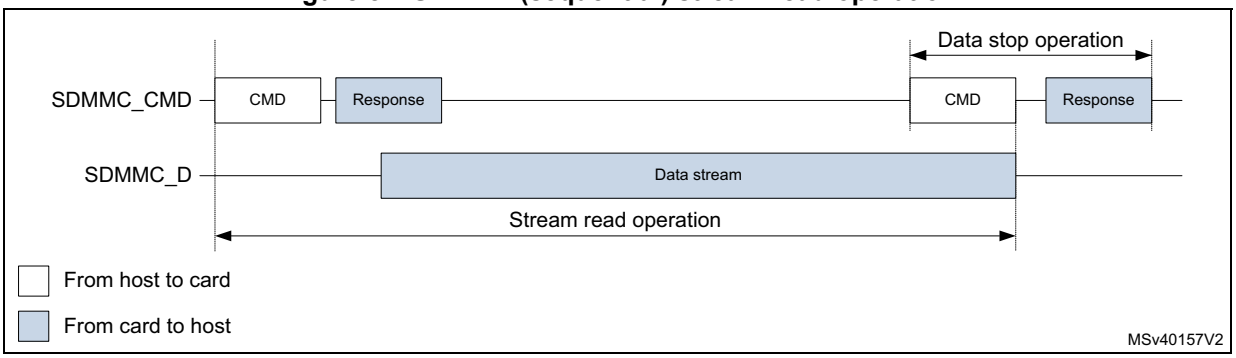
Note: The Stop Transmission command is not required at the end of a e•MMC multiple block read with predefined block count.

Figure 86. SDMMC (multiple) block write operation

Note: The Stop Transmission command is not required at the end of an e•MMC multiple block write with predefined block count.

The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 87. SDMMC (sequential) stream read operation



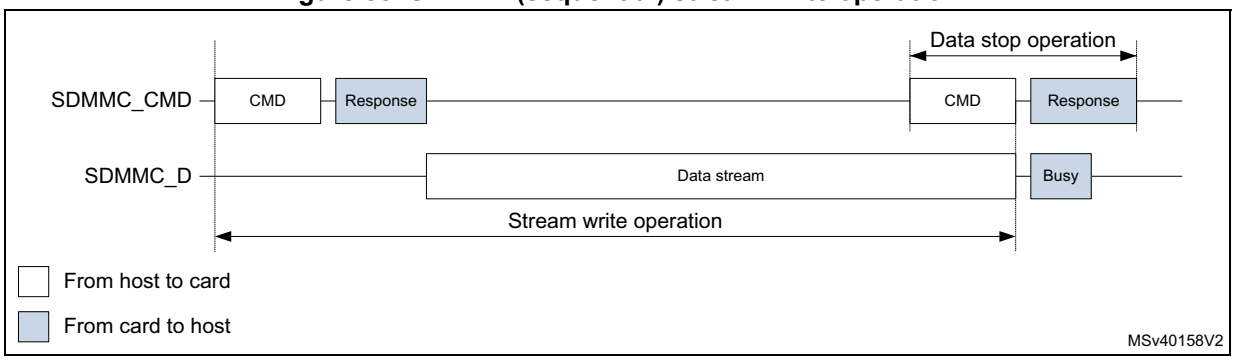


Figure 88. SDMMC (sequential) stream write operation

Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).

20.4 SDMMC operation modes

Table 146. SDMMC operation modes SD and SDIO

SDIO bus speed modes(1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V]
DS (default speed)	12.5	25	3.3
HS (high speed)	25	50	3.3
SDR12	12.5	25	1.8
SDR25	25	50	1.8
DDR50	50	50	1.8
SDR50	50	100	1.8
SDR104	104	208	1.8

1. SDR single data rate signaling.
2. DDR double data rate signaling (data is sampled on both SDMMC_CK clock edges).
3. SDIO bus speed with 4-bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.

SDR104 mode requires variable delay support using sampling point tuning. The use of variable delay is optional for SDR50 mode.

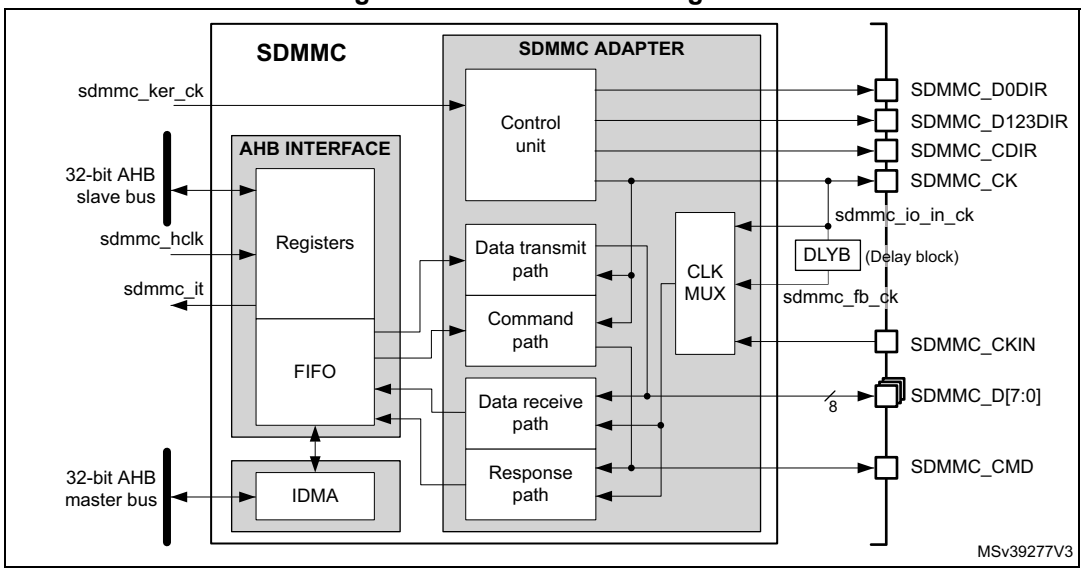
Table 147. SDMMC operation modes *e*•MMC

e•MMC bus speed modes (1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V](5)
Legacy compatible	26	26	3/1.8/1.2V
High speed SDR	52	52	3/1.8/1.2V
High speed DDR	104	52	3/1.8/1.2V
High speed HS200	200	200	1.8/1.2V

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. *e*•MMC bus speed with 8-bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.

20.5 SDMMC functional description



The SDMMC consists of four parts:

- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the *e*•MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

20.5.1 SDMMC block diagram

Figure 89 shows the SDMMC block diagram.

Figure 89. SDMMC block diagram

20.5.2 SDMMC pins and internal signals

Table 148 lists the SDMMC internal input/output signals, *Table 149* the SDMMC pins (alternate functions).

Table 148. SDMMC internal input/output signals

Signal name	Signal type	Description
sdmmc_ker_ck	Digital input	SDMMC kernel clock
sdmmc_hclk	Digital input	AHB clock
sdmmc_it	Digital output	SDMMC global interrupt

Table 148. SDMMC internal input/output signals (continued)

Signal name	Signal type	Description
sdmmc_io_in_ck	Digital input	SD/SDIO/*e*•MMC card feedback clock. This signal is internally connected to the SDMMC_CK pin (for DS and HS modes).
sdmmc_fb_ck	Digital input	SD/SDIO/*e*•MMC card tuned feedback clock after DLYB delay block (for SDR50, DDR50, SDR104, HS200)

Table 149. SDMMC pins

Pin name	Pin type	Description
SDMMC_CK	Digital output	Clock to SD/SDIO/*e*•MMC card
SDMMC_CKIN	Digital input	Clock feedback from an external driver for SD/SDIO/*e*•MMC card. (for SDR12, SDR25, SDR50, DDR50)
SDMMC_CMD	Digital input/output	SD/SDIO/*e*•MMC card bidirectional command/response signal.
SDMMC_CDIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_CMD signal.
SDMMC_D[7:0]	Digital input/output	SD/SDIO/*e*•MMC card bidirectional data lines.
SDMMC_D0DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_D0 data line.
SDMMC_D123DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the data lines SDMMC_D[3:1].

20.5.3 General description

The **SDMMC_D[7:0]** lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an *e*•MMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The **SDMMC_D0DIR** signal indicates the I/O direction for the SDMMC_D0 data line, the **SDMMC_D123DIR** for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal **SDMMC_CDIR**.

SDMMC_CK clock to the card originates from **sdmmc_ker_ck**:

- When the sdmmc_ker_ck clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the sdmmc_ker_ck duty cycle is not 50 %, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC_CMD / SDMMC_D[7:0] outputs and the SDMMC_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See *Figure 90*.

Figure 90. SDMMC Command and data phase relation

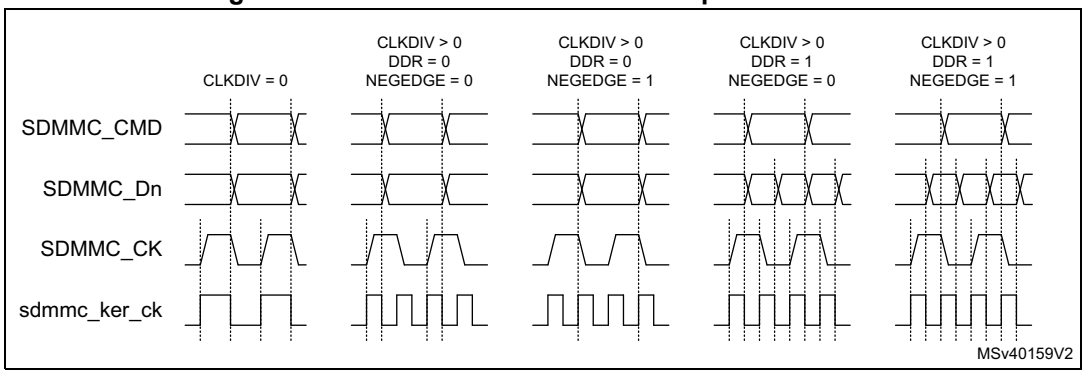


Table 150. SDMMC Command and data phase selection

CLKDIV	DDR	NEGEDGE	SDMMC_CK	Command out	Data out
0	x	x	= sdmmc_ker_ck	Generated on sdmmc_ker_ck falling edge	
>0	0	0	Generated on sdmmc_ker_ck rising edge	Generated on sdmmc_ker_ck falling edge succeeding the SDMMC_CK rising edge.	
		1		Generated on the same sdmmc_ker_ck rising edge that generates the SDMMC_CK falling edge.	
	1	0		Generated on sdmmc_ker_ck falling edge succeeding the SDMMC_CK rising edge.	Generated on sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
		1		Generated on the same sdmmc_ker_ck rising edge that generates the SDMMC_CK falling edge.	

By default, the **sdmmc_io_in_ck** feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between **sdmmc_io_in_ck** signal (DLYB input dlyb_in_ck) and **sdmmc_fb_ck** clock input of SDMMC (DLYB output dlyb_out_ck). Selecting the **sdmmc_fb_ck** clock input in the receive path then enables using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

When using an external driver (a voltage switch transceiver), the SDMMC_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/*e*•MMC card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).

Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

20.5.4 SDMMC adapter

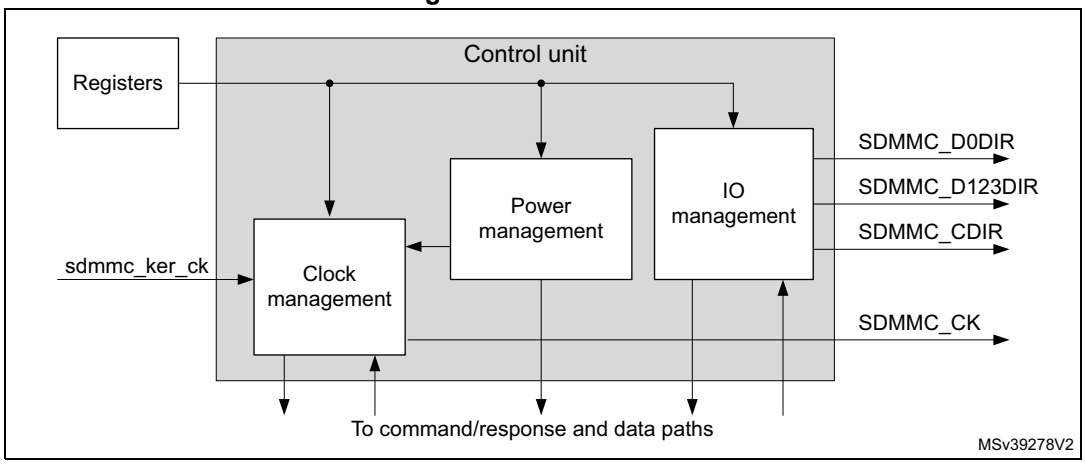
The SDMMC adapter (see *Figure 89: SDMMC block diagram*) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

Note: The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

Adapter register block



The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

Control unit

The control unit illustrated in *Figure 91*, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.

Figure 91. Control unit

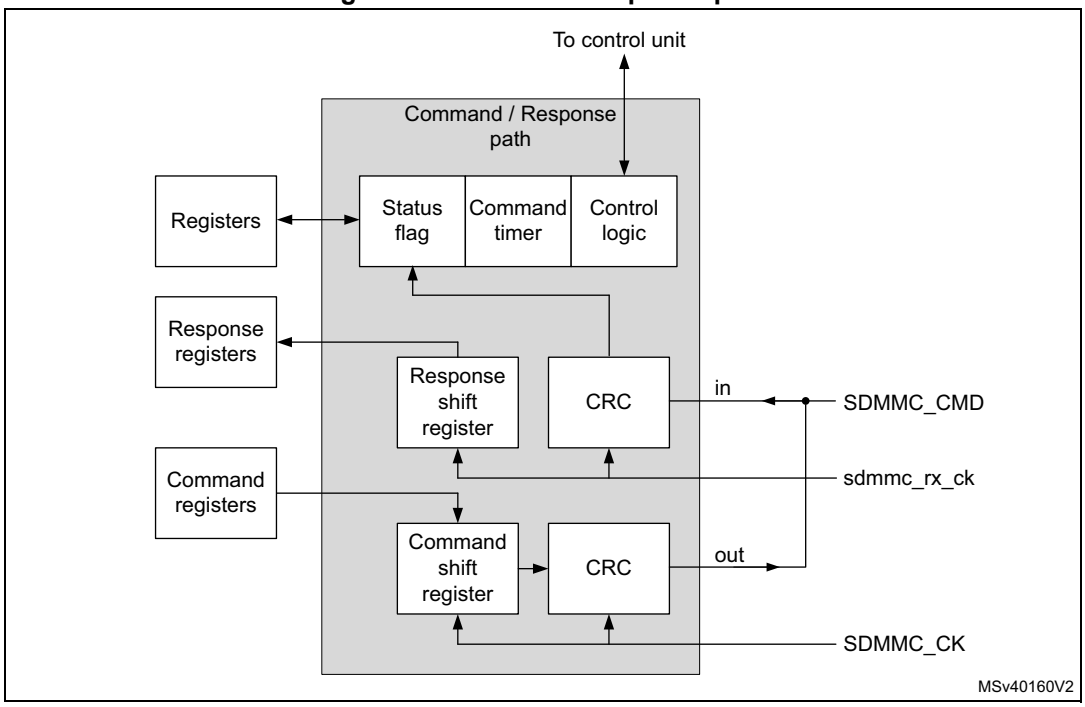
The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:

- power-off
- power-up
- power-on

The clock management subunit uses the sdmmc_ker_ck to generate the SDMMC_CK and provides the division control. It also takes care of stopping the SDMMC_CK for flow control, for example.

The clock outputs are inactive:



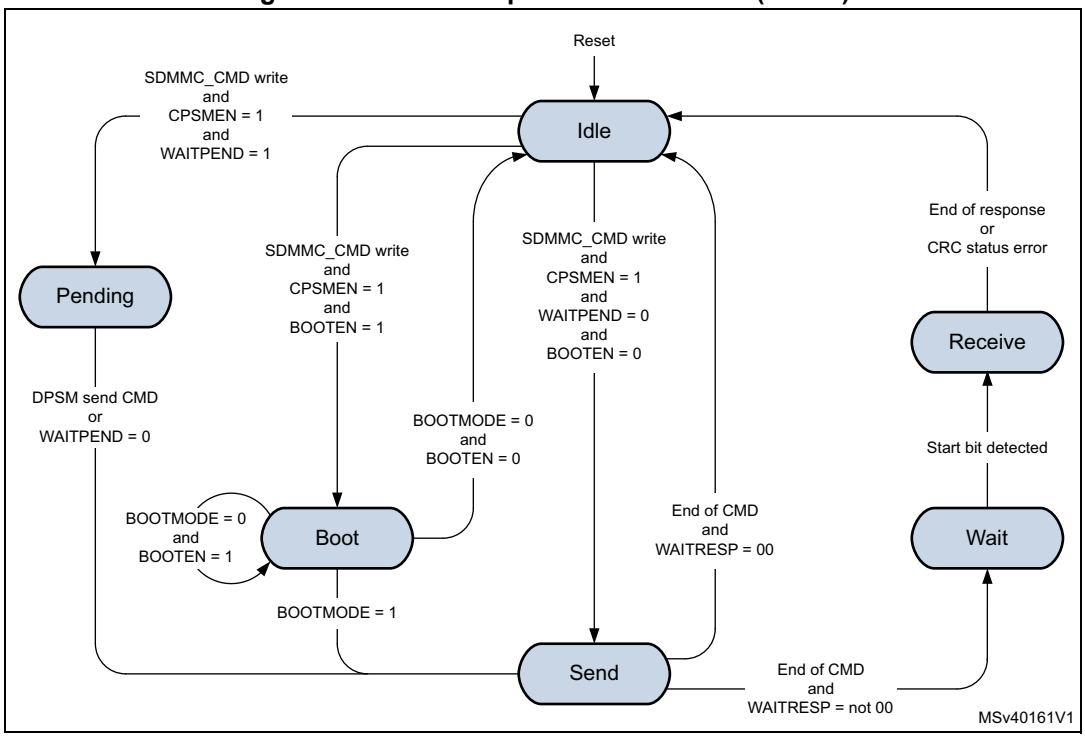
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit PWRSAV) is enabled and the card bus is in the Idle state for eight clock periods. The clock is stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock is restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the SDMMC_Dn and SDMMC_CMD I/O direction signals, which controls the external voltage transceiver.

Command/response path

The command/response path subunit transfers commands and responses on the SDMMC_CMD line. The command path is clocked on the SDMMC_CK and sends commands to the card,. The response path is clocked on the sdmmc_rx_ck and receives responses from the card.

Figure 92. Command/response path



Command/response path state machine (CPSM):

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.
- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active (not in the Idle state), the CPSMACT bit is set.

Figure 93. Command path state machine (CPSM)

- **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  - to the Send state when WAITPEND = 0 and BOOTEN = 0.
  - to the Pending state when WAITPEND = 1.
  - to the Boot state when BOOTEN = 1.
- **Send**: The command is sent and the CRC is appended.
  - When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM at the end of the command.
  - When the CMDTRANS bit is set and the CMDSUSPEND bit is 0 the interrupt period is terminated at the end of the command.
  - When CMDSTOP bit is set the CPSM Abort signal is issued to the DPSM at the end of the command.
  - If no response is expected (WAITRESP = 00) the CPSM moves to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 and BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command end bit, otherwise the

CMDSENT flag is generated immediately after the command end bit.
The RESPCMDR and RESPxR registers are not modified.

– If a command response is expected (WAITRESP = not 00) the CPSM moves to the Wait state and start the response timeout.

- **Wait**: The command path waits for a response.
  – When WAITINT bit is 0 the command timer starts running and the CPSM waits for a start bit.
  a) If a start bit is detected before the timeout the CPSM moves to the Receive state.
  b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are not modified.
  – When WAITINT bit is 1, the timer is disabled and the CPSM waits for an interrupt request (response start bit) from one of the cards.
  a) When a start bit is detected the CPSM moves to the Receive state.
  b) When writing WAITINT to 0 (interrupt mode abort), the host sends a response by its self and on detecting the start bit the CPSM move to the Receive state.
- **Receive**: The command response is received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present is verified against the internally generated CRC code.
  – When the CMDSUSPEND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period is started after the response.
  When the CMDSUSPEND bit is cleared, or the CMDSUSPEND bit is 1 and the SDIO Response bit BS = 1 (response bit [39]), there is no interrupt period started.
  – When the CMDTRANS bit is set and the CMDSUSPEND bit is set and the SDIO Response bit DF= 1 (response bit [32]) the interrupt period is terminated after the response.
  – When the CRC status passes or no CRC is present the CMDREND flag is set, the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are updated with received response.
  - When BOOTMODE = 1 and BOOTEN = 0 the CMDREND flag is delayed 56 cycles after the response end bit, otherwise the CMDREND flag is generated immediately after the response end bit.
  - When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal is issued to the DPSM at the end of the command response.
  – When the CRC status fails the CCRCFAIL flag is set and the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are updated with received response.
- **Pending**: According the pending WAITPEND bit in the command register, the CPSM enters the pending state.
  – When DATALENGTH ≤ 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
  – When DATALENGTH > 5 bytes, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the

DPSM before moving to the Send state. This enables, for example, the CMD12 Stop Transmission command to be sent aligned with the data.

– When writing WAITPEND to 0, the CPSM moves to the Send state.

- **Boot**: If the BOOTEN bit is set in the command register, the CPSM enters the Boot state, and when:
  – BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal is issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.
  – BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

Note: The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the N_{CC} and N_{RC} timing constraints. N_{CC} is the minimum delay between two host commands, and N_{RC} is the minimum delay between the host command and the card response.

The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for *e*•MMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and *e*•MMC cards is shown in *Table 151.*

The command token data is taken from two registers, one containing a 32-bit argument and the other containing the 6-bit command index (six bits sent to a card).

Table 151. Command token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	1	Transmission bit
[45:40]	6	x	Command index
[39:8]	32	x	Argument
[7:1]	7	x	CRC7
0	1	1	End bit

Next to the command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various

coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and *e*•MMC cards are shown in *Table 152*, *Table 153* and *Table 154*.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

The response token data is stored in five registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

Table 152. Short response with CRC token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	0	Transmission bit
[45:40]	6	x	Command index (or reserved 111111)
[39:8]	32	x	Argument
[7:1]	7	x	CRC7
0	1	1	End bit

Table 153. Short response without CRC token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	0	Transmission bit
[45:40]	6	x	Command index (or reserved 111111)
[39:8]	32	x	Argument
[7:1]	7	1111111	(reserved 1111111)
0	1	1	End bit

Table 154. Long response with CRC token format

Bit position	Width	Value	Description
135	1	0	Start bit
134	1	0	Transmission bit
[133:128]	6	111111	Reserved
[127:1]	127:8	x	CID or CSD slices
	7:1	x	CRC7 (included in CID or CSD)
0	1	1	End bit

The command/response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the

SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see *Figure 90*.

The command and short response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmission bit, command index, and command argument (or card status).

For the long response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmission bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:

CRC[6:0] = remainder $[(M(x) * x^7) / G(x)]$

$G(x) = x^7 + x^3 + 1$

$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit before CRC}) * x^0$

Where n = 39 or 119.

The CPSM can send a number of specific commands to handle various operating modes when CPSMEN is set, see *Table 155*.

Table 155. Specific Commands overview

VSWITCH	BOOTEN	BOOTMOD	CMDTRAN	WAITPEND	CMDSTOP	WAITINT	Description
1	x	x	x	x	x	x	Start voltage switch sequence
0	1	x	x	x	x	x	Start normal boot
0	1	1	x	x	x	x	Start alternative boot
0	0	1	x	x	x	x	Stop alternative boot.
0	0	0	1	x	x	x	Send command with associated data transfer.
0	0	0	0	1	1	x	*e*•MMC stream data transfer, command (STOP_TRANSMISSION) pending until end of data transfer.
0	0	0	0	1	0	x	*e*•MMC stream data transfer, command different from (STOP_TRANSMISSION) pending until end of data transfer.
0	0	0	0	0	1	x	Send command (STOP_TRANSMISSION), stopping any ongoing data transmission.
0	0	0	0	0	0	1	Enter *e*•MMC wait interrupt (Wait-IRQ) mode.
0	0	0	0	0	0	0	Any other none specific command

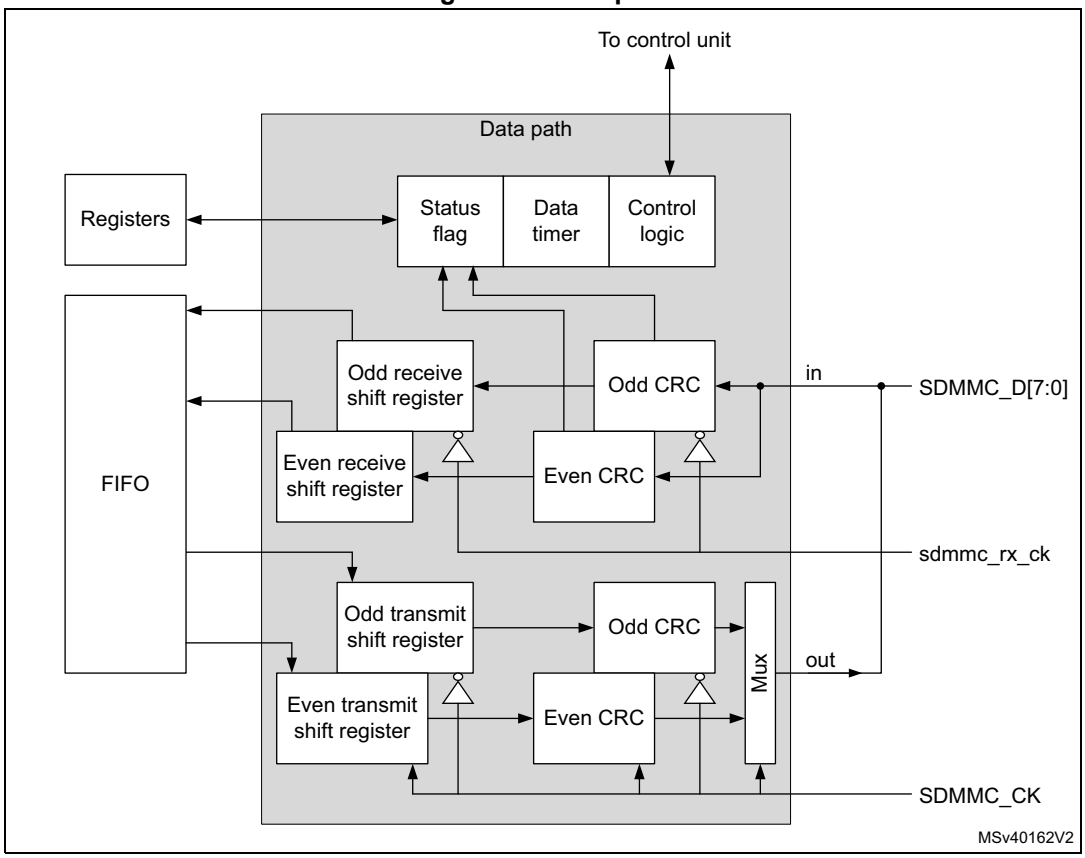
The command/response path implements the status flags and associated clear bits shown in *Table 156*:

Table 156. Command path status flags

Flag	Description
CMDSENT	Set at the end of the command without response (CPSM moves from Send to Idle).
CMDREND	Set at the end of the command response when the CRC is OK (CPSM moves from Receive to Idle).
CCRCFAIL	Set at the end of the command response when the CRC is FAIL (CPSM moves from Receive to Idle).
CTIMEOUT	Set after the command when no response start bit received before the timeout (CPSM moves from Wait to Idle).
CKSTOP	Set after the voltage switch (VSWITCHEN = 1) command response when the CRC is OK and the SDMMC_CK is stopped (no impact on CPSM).
VSWEND	Set after the voltage switch (VSWITCH = 1) timeout of 5 ms + 1 ms (no impact on CPSM).
CPSMACT	Command transfer in progress (CPSM not in Idle state).

The command path error handling is shown in *Table 157*:

Table 157. Command path error handling



Error	CPSM state	Cause	Card action	Host action	CPSM action
Timeout	Wait	No start bit in time	Unknown	Reset or cycle power card(1)	Move to Idle
CRC status	Receive	Negative status	Command ignored	Resend command(1)	Move to Idle
		Transmission error	Command accepted	Resend command(1)	

1. When CMDTRANS is set, also a stop_transmission command must be send to move the DPSM to Idle.

Data path

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. *Figure 94* shows the data path block diagram.

Figure 94. Data path

The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

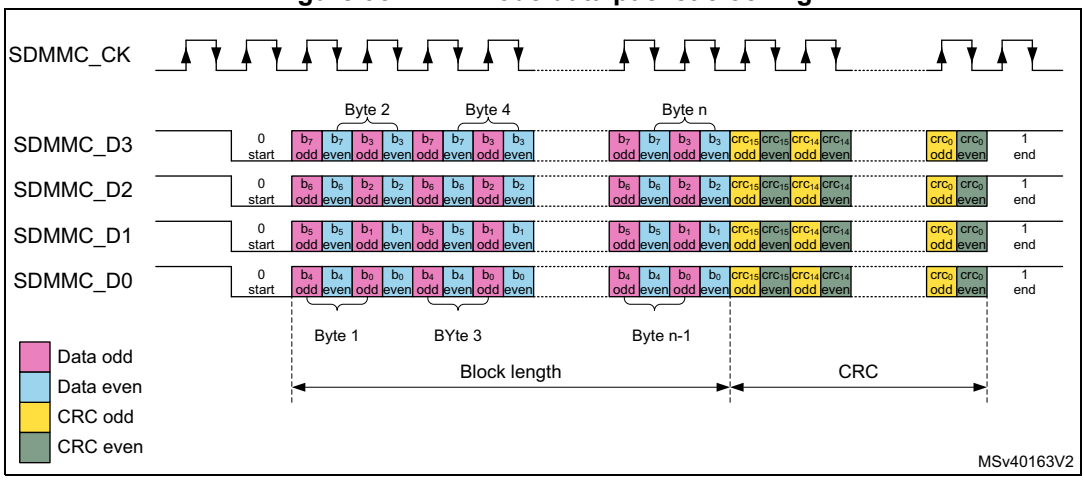
Note: The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)

In DDR mode, data is sampled on both edges of the SDMMC_CK according the following rules, see also *Figure 95* and *Figure 96*:

- On the rising edge of the clock odd bytes are sampled.
- On the falling edge of the clock even bytes are sampled.
- Data payload size is always a multiple of 2 bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, end bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode, the SDMMC_CK clock division must be ≥ 2.

Figure 95. DDR mode data packet clocking



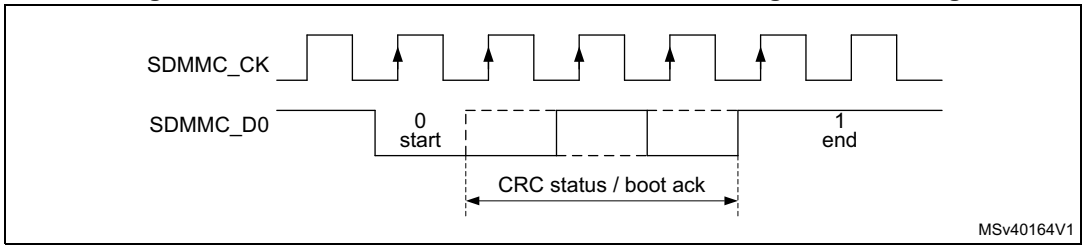


Figure 96. DDR mode CRC status / boot acknowledgment clocking

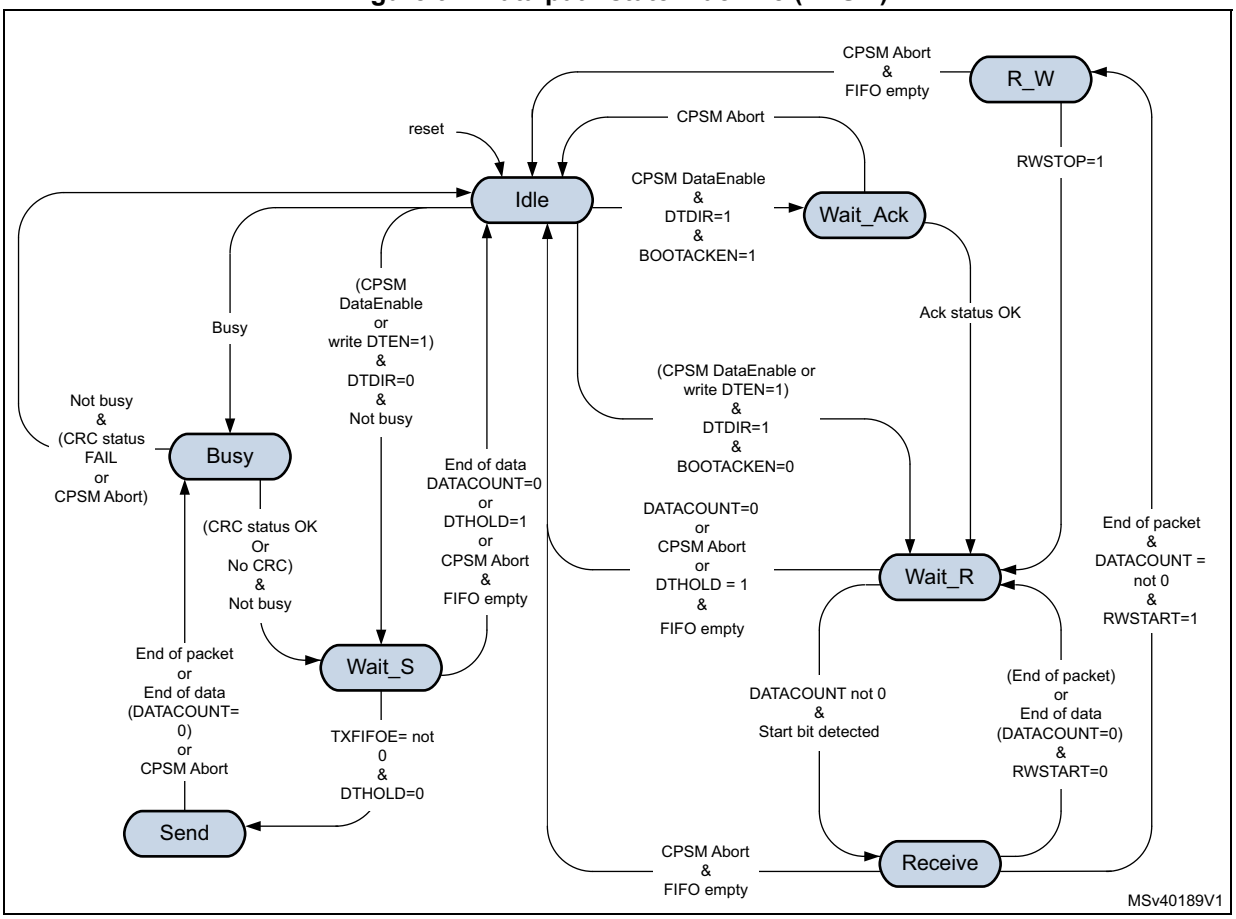
Data path state machine (DPSM)



Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait_S or Wait_R state when it is enabled:

- Send: the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.

For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in *Figure 97*. When ever the DPSM is active (not in the Idle state), the DPSMACT bit is set.

Figure 97. Data path state machine (DPSM)

- **Idle** state: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM is activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

  When not busy, the DPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:

  – When the data direction bit (DTDIR) indicates send, moves to the Wait_S.

  – When the data direction bit (DTDIR) indicates receive, moves to the
  - Wait_R when BOOTACKEN register bit is clear.
  - Wait_Ack when BOOTACKEN register bit is set and start the acknowledgment timeout.

  When busy the DPSM keeps the SDMMC_CK clock active and move to the Busy state.

Note: DTEN must not be used to start data transfer with SD, SDIO and e•MMC cards.

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.
- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATALENGTH.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATALENGTH.
  - if the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DTIMEOUT) and the DPSM stays in the Wait_R state.
  - If the CPSM Abort signal is set:
    If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST, and sets the DABORT flag.
    If DATACOUNT is zero normal operation is continued, there is no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFORST, and issues the DHOLD flag. When holding the timeout is disabled. When an CPSM Abort signal is received during holding, the transfer is aborted.

- When DATACOUNT = 0, the transfer is completed normally and there is no DHOLD flag.

– When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **R_W** state: the data path Read Wait the bus.
  – The DPSM moves to the Wait_R state when the Read Wait stop bit (RWSTOP) is set, and start the receive timeout.
  – If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.
- **Receive** state: the data path receives serial data from a card. Pack the data in bytes and written it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  – In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  – In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.

  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
  - R_W state when RWSTART = 1 and DATACOUNT > zero, the DBCKEND flag is set.
  - Wait_R state otherwise.

  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
  - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
  - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.

  – In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.
  – When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.
  – When an CPSM Abort signal is received:
  - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
  - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT = 0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.
  – When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **Wait_S** state: the data path waits for data to be available from the FIFO.
  - If the data counter DATACOUNT > 0, waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
  - If the data counter (DATACOUNT) = 0 the DPSM moves to the Idle state.
    - When DTHOLD is disabled, the DATAEND flag is set.
    - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM moves to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM moves to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and DATACOUNT = 0 the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT = 0, normal operation is continued, there is no DABORT flag since the transfer has completed normally.

Note: The DPSM remains in the Wait_S state for at least two clock periods to meet the N_{WR} timing requirements, where N_{WR} is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- **Send** state: the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter DATACOUNT > 0. When the data counter reaches zero moves to the Busy state and start the transmit timeout.
    Before sending the last stream byte according to DATACOUNT, the DPSM issues a trigger on the send CMD signal. This signal is used by the CPSM to sent any pending command (CMD12 Stop Transmission command).
  - If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDERR). The DPSM stays in the Send state.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the transfer with DATACOUNT = 0, the transfer is aborted. The DPSM sends a last data bit followed by an end bit. The FIFO is disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer

with DATACOUNT = 0, the transfer is completed normally, there is no DABORT flag.

- **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:
  - If a CRC status token is expected and indicate “non-erroneous transmission” or when there is no CRC expected:
    - it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
    - When the card is busy SDMMC_D0 is low it remains in the Busy state.
  - If a CRC status token is expected and indicates “erroneous transmission”.
    - When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO is disabled/flushed and the DPSM stays in the Busy state.
    - When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - If a busy timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - When receiving the CPSM Abort signal in the Busy state:
    - If the CPSM Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT = 0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
    - If the CPSM Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
  - When entering the Busy state due to an abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.
  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.
  - When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.

The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received withing 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.
- When receiving data, the timeout occurs
  - when there is still data to be received DATACOUNT > 0 and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.
- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.

When DATATIME = 0:

- In receive the start bit must be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

Table 158. Data token format

Description	Start bit	Data(1)	CRC16	End bit	DTMODE
Block data	0	(DBLOCKSIZE, DATALENGTH)	Yes	1	00
SDIO multibyte	0	(DATALENGTH)	Yes	1	01
e•MMC stream	0	(DATALENGTH)	No	1	10

1. The total amount of data to transfer is given by DATALENGTH. Where for Block data the amount of data in each block is given by DBLOCKSIZE.

The data token format is selected with register bits DTMODE according.

The data path implements the status flags and associated clear bits shown in *Table 159*:

Table 159. Data path status flags and clear bits

Flag		Description
DATAEND	TX	Set at the end of the complete data transfer when the CRC is OK and busy has finished and both DTHOLD = 0 and DATACOUNT = 0. (DPSM moves from Wait_S to Idle)
	RX	Set at the end of the complete data transfer when the CRC is OK and all data has been read, (DATACOUNT = 0 and FIFO is empty). (DPSM moves from Wait_R to Idle)
	Boot	

Table 159. Data path status flags and clear bits (continued)

Flag		Description
DCRCFAIL	TX	Set at the end of the CRC when FAIL and busy has finished. (DPSM stay in Busy when there is still data to send and wait for CPSM Abort) (DPSM moves from Busy to Idle when all data has been sent) or DPSM has been started with DTEN
	RX	Set at the end of the CRC when FAIL and FIFO is empty. (DPSM stays in Receive when there is still data to be received and wait for CPSM Abort) (DPSM moves from Receive to Idle when all data has been received or DPSM has been started with DTEN)
	Boot	
ACKFAIL	Boot	Set at the end of the boot acknowledgment when fail. (DPSM stays in Wait_Ack and wait for CPSM Abort)
DTIMEOUT	CMD R1b	Set after the command response no end of busy received before the timeout. (DPSM stays in Busy and wait for CPSM Abort)
	TX	Set when no CRC token start bit received within Ncrc, or no end of busy received before the timeout. (DPSM stays in Busy and wait for CPSM Abort) (When DPSM has been started with DTEN move to Idle) Note: The DCRCFAIL flag may also be set when CRC failed before the busy timeout.
	RX	Set when no start bit received before the timeout. (DPSM stays in Wait_R and wait for CPSM Abort) (When DPSM has been started with DTEN move to Idle)
	Boot	
ACKTIMEOUT	Boot	Set when no start bit received before the timeout. (DPSM stays in Wait_Ack and wait for CPSM Abort)
DBCKEND	TX	When DTHOLD = 1 and IDMAEN = 0: Set at the end of data block transfer when the CRC is OK and busy has finished, when data transfer is not complete (DATACOUNT >0). (DPSM moves from Busy to Wait_S)
	RX	When RWSTART = 1: Set at the end of data block transfer when the CRC is OK, when data transfer is not complete (DATACOUNT > 0). (DPSM moves from Receive to R_W)
	Boot	
DHOLD	TX	When DTHOLD = 1: Set at the end of data block transfer when the CRC is OK and busy has finished. (DPSM moves from Wait_S to Idle)
	RX	When DTHOLD = 1: Set at the end of data block transfer when the CRC is OK and all data has been read (FIFO is empty), when data transfer is not complete (DATACOUNT >0). (DPSM moves from Wait_R to Idle)
DABORT	CMD R1b	When CPSM Abort event has been sent by the CPSM and busy has finished. (DPSM moves from Busy to Idle)
	TX	When CPSM Abort event has been sent by the CPSM before the 2 last bits of the transfer. (DPSM moves from any state to Idle)
	RX	
	Boot	
BUSYD0END	CMD R1b	Set after the command response when end of busy before the timeout. (DPSM moves from Busy to Idle)
DPSMACT		Data transfer in progress. (DPSM not in Idle state)

The data path error handling is shown in *Table 160*:

Table 160. Data path error handling

Error	DPSM state	Cause	Card action	Host action	DPSM action
Timeout	Wait_Ack	No Ack in time	unknown	Card cycle power	Stay in Wait_Ack (reset the SDMMC with the RCC.SDMMCxRST register bit)
	Wait_R	No start bit in time	unknown	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
			unknown	Stop boot procedure	
	Busy	Busy too long (due to data transfer)	unknown	Stop data reception Send stop transmission command	
		Busy too long (due to R1b)	unknown	Send reset command	
CRC	Receive	transmission error	Send further data	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
CRC status	Busy	Negative status	Ignore further data	Stop data transmission Send stop transmission command	On CPSM Abort move to Idle
		transmission error	wait for further data		
Ack status	Wait_Ack	transmission error	Send boot data	Stop boot procedure	On CPSM Abort move to Idle
Overrun	Receive	FIFO full	Send further data	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
Underrun	Send	FIFO empty	Receive further data	Stop data transmission Send stop transmission command	On CPSM Abort move to Idle

Data FIFO

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contain a 32-bit wide, 16-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.

The FIFO can be in one of the following states:

- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)

The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see *Table 161*.

Table 161. Data FIFO access

Data FIFO access	IDMAEN
From firmware via AHB slave interface	0
From IDMA via AHB master interface	1

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out. The transmit FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in transmit mode (DTDIR = 0).
   – Configures the FIFO in transmit mode.
3. Enable the data transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit
4. When (DPSMACT = 1) write data to the FIFO.
   – The DPSM stays in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by DATALENGTH.

- The SDMMC keeps sending data as long as FIFO is not empty, hardware flow control during data transfer is used to prevent FIFO underrun.

5. Write data to the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.
6. When last data has been written wait for end of data (DATAEND flag)
   – SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, firmware must stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in *Table 162*.

Table 162. Transmit FIFO status flags

Flag	Description
TXFIFOF	Set to high when all transmit FIFO words contain valid data.
TXFIFOE	Set to high when the transmit FIFO does not contain valid data.
TXFIFOHE	Set to high when half or more transmit FIFO words are empty.
TXUNDERR	Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.

Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface.When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses.

The receive FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
3. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
4. When (DPSMACT = 1) the FIFO is ready to receive data.
   – The DPSM writes the received data to the FIFO.
   - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
5. Read data from the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
   - When last data has been received, read data from the FIFO until FIFO is empty (DATAEND = 1).
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.
6. SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer hold when IDMAEN = 0, the firmware must read the remaining data until the FIFO is empty and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

In case of a data transfer error when IDMAEN = 0, the firmware must stop reading the FIFO and flush and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

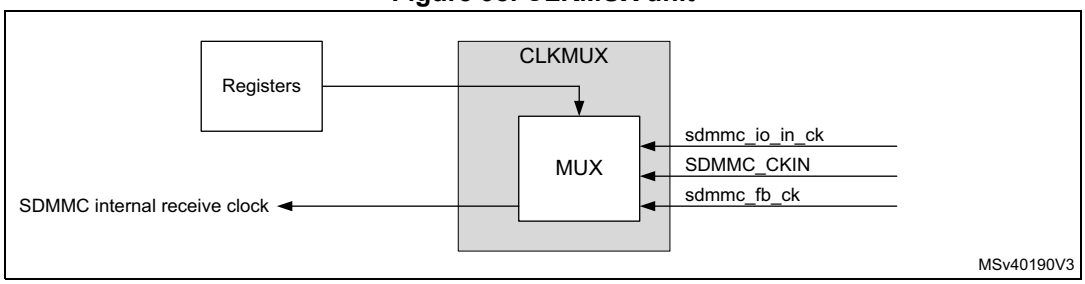
The receive FIFO status flags are listed in *Table 163*.

Table 163. Receive FIFO status flags

Flag	Description
RXFIFOF	Set to high when all receive FIFO words contain valid data
RXFIFOE	Set to high when the receive FIFO does not contain valid data.
RXFIFOHF	Set to high when half or more receive FIFO words contain valid data.
RXOVERR	Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.

CLKMUX unit

The CLKMUX selects the source for clock sdmmc_rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKRX, between:



- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.

The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb_ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

Figure 98. CLKMUX unit

The sdmmc_rx_ck source must be changed when the CPSM and DPSM are in the Idle state.

20.5.5 SDMMC AHB slave interface

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

SDMMC FIFO

The FIFO access is restricted to word access only:

- In transmit FIFO mode
  - Data are written to the FIFO in words (32-bits) until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.
- In receive FIFO mode
  - Data are read from the FIFO in words (32-bits) until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

20.5.6 SDMMC AHB master interface

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.

SDMMC IDMA

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 8 beats.

- In transmit burst transfer mode:
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller then burst size data is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.
- In receive burst transfer mode:
  - Data are stored in burst in to memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller then burst size data, is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- linked list channel

Single buffered channel

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

Linked list channel

In linked list configuration, IDMAMODE = 1, the data at the memory side is subsequently accessed from linked buffers, located at base address IDMABASE. The size of the memory buffers is defined by IDMABSIZE. The buffer size must be an integer multiple of the burst size. The bit ULA is used to indicate if a new linked list buffer configuration has to be loaded from the linked list table. A new linked list configuration is loaded when the ULA bit for the current linked list item is set.

The first linked list item configuration is programmed by firmware directly in the SDMMC registers.

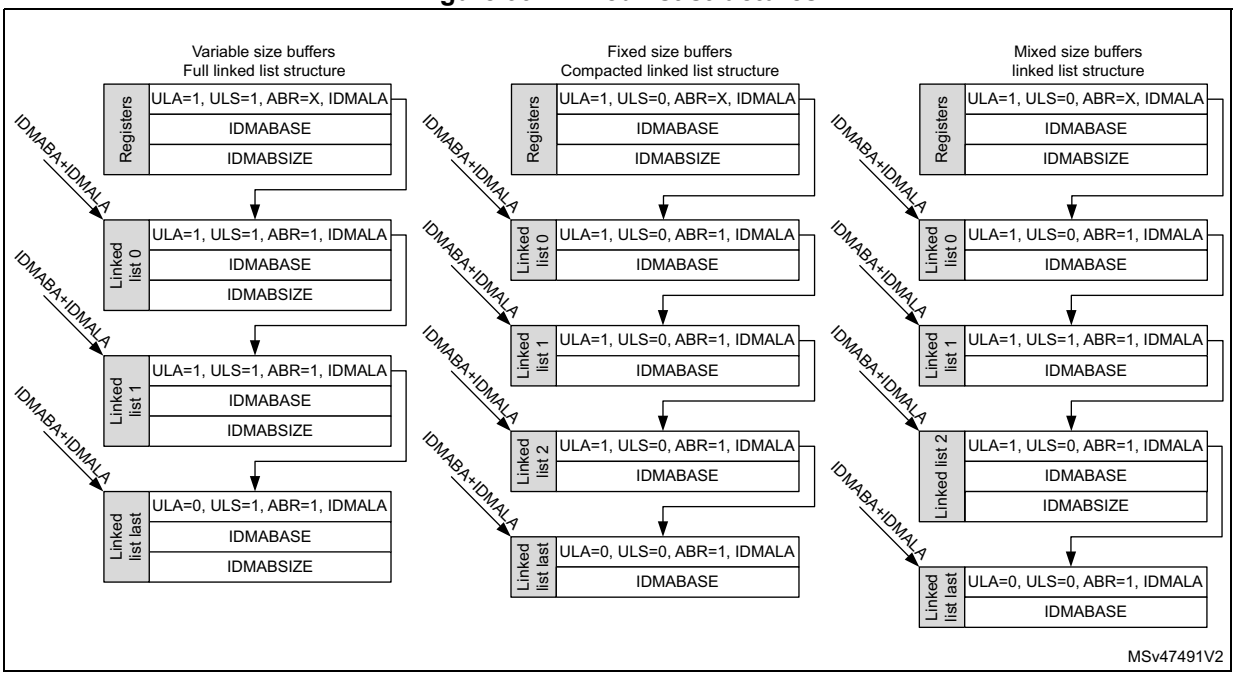
When the IDMA has finished transferring all the data of one linked list buffer, according IDMABSIZE, and when the linked list item ULA bit is set, the IDMA loads the new linked list item from the linked list table, and continues transferring data from the next linked list buffer.

When the IDMA has finished transferring all data, according IDMABSIZE and ULA, and the DPSM has completed the transfer, according DATALENGHT, the DATAEND flag is set.

In the following cases, the linked list provides more buffer space than the data to transfer which means the current linked list buffer data has not completely be transfered:

- the ULA bit is set, and all SDMMC data according DATALENGTH has been transfered (DATAEND flag)
- a transfer error (DCRCFAIL when DATACOUNT > 0, RXOVERR, TXUNDERR) occurs
- a transfer is hold (DTHOLD)

In all above cases, the IDMA linked list is stopped and the FIFO is flushed/reset. Before starting or restarting a new SDMMC transfer, the software must initialize a new linked list with correct IDMABASE and IDMABSIZE.



When a IDMA transfer error occurs (see *Section : IDMA transfer error management*) or when the linked list does not provide sufficient buffer space:

- the linked list ends with ULA = 0 and all last linked list buffer data has been transfered, and not all SDMMC data according DATALENGTH has been transfered. The SDMMC transfer is stopped and an IDMA transfer error is generated (see *Section : IDMA transfer error management*).

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZE, resulting in a 3-word linked list structure. When the IDMABSIZE is not to be loaded (fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

Figure 99. Linked list structures

There is no restriction on mixing both linked list item structures in a single list, this enables the IDMABSIZE to be updated only when needed.

Whenever a linked list buffer has been transfered and the current buffer ULA = 1, an end-of-linked-list-buffer-transfer-complete interrupt (IDMABTC) may be generated (if interrupt is enabled).

Linked list acknowledgment

In the case where software dynamically updates the linked list, during the SDMMC transfer, the availability of a new linked list buffer can be acknowledged by the acknowledge buffer ready (ABR) bit.

When ABR acknowledges that the new linked list buffer is ready, the IDMA continues transferring data from the new linked list buffer.

When ABR indicates that the new linked list buffer is not ready, an IDMA transfer error is generated (see *Section : IDMA transfer error management*). Depending when the IDMA transfer error occurs, it normally causes the generation of an TXUNDERR or RXOVERR error. When a linked list buffer is not acknowledged in time the SDMMC transfer is stopped.

The ABR information is “don't care” when starting the linked list from software programmed register information. The first linked list buffer must be ready to be used before starting the SDMMC transfer.

IDMA transfer error management

An IDMA transfer error can occur:

- When reading or writing a reserved address space (for data or linked list information).
- When there is no more linked list buffer space to store received SDMMC data.
- When all linked list buffer data has been transfered and still more SDMMC data needs to be sent.
- When the availability of a linked list buffer is not acknowledged.

On an IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set and hardware flow control is disabled. Depending when the IDMA transfer error occurs, it normally causes the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.
- An IDMA transfer error is detected during a STOP_TRANSNMISSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.
- An IDMA transfer error is detected at the end of the SDMMC transfer (DHOLD, or DATAEND).
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHOLD or DATAEND flag is set.

The IDMATE is generated on an other SDMMC transfer interrupt (TXUNDERR. RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).

20.5.7 AHB and SDMMC_CK clock relation

The AHB must at least have 3x more bandwidth than the SDMMC bus bandwidth: for example, for SDR50 4-bit mode (50 Mbyte/s), the minimum sdmmc_hclk frequency is 37.5 MHz (150 Mbyte/s).

Table 164. AHB and SDMMC_CK clock frequency relation

SDMMC bus mode	SDMMC bus width	Maximum SDMMC_CK [MHz]	Minimum AHB clock [MHz]
e•MMC DS	8	26	19.5
e•MMC HS	8	52	39
e•MMC DDR52	8	52	78
e•MMC HS200	8	200	150
SD DS / SDR12	4	25	9.4
SD HS / SDR25	4	50	18.8
SD DDR50	4	50	37.5
SD SDR50	4	100	37.5
SD SDR104	4	208	78

20.6 Card functional description

20.6.1 SD I/O mode

The following features are SDMMC specific operations:

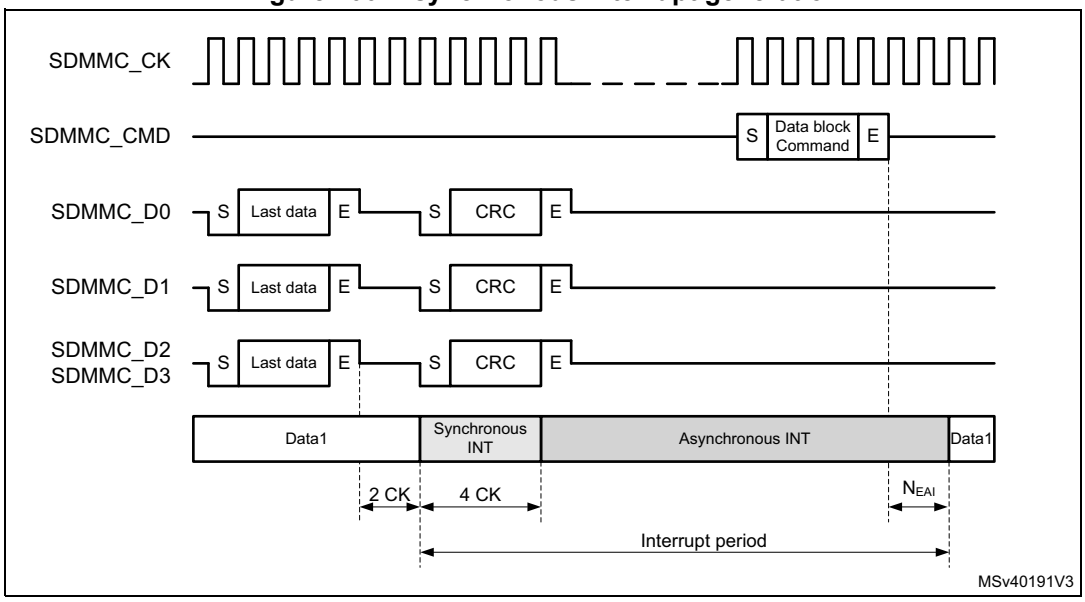
- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO Read Wait operation by stopping the clock
- SDIO Read Wait operation by SDMMC_D2 signaling

Table 165. SDIO special operation control

Operation mode	SDIOEN	RWMOD	RWSTOP	RWSTART	DTDIR
Interrupt detection	1	X	X	X	X
Suspend/Resume operation	X	X	X	X	X
Read Wait SDMMC_CK clock stop (START)	X	1	0	1	1
Read Wait SDMMC_CK clock stop (STOP)	X	1	1	1	1
Read Wait SDMMC_D2 signaling (START)	X	0	0	1	1
Read Wait SDMMC_D2 signaling (STOP)	X	0	1	1	1

SD I/O interrupts

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or deasserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).



In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in *Table 165*.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.

- Synchronous interrupt, require the SDMMC_CK to be active.
- Asynchronous interrupt, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.

Figure 100. Asynchronous interrupt generation

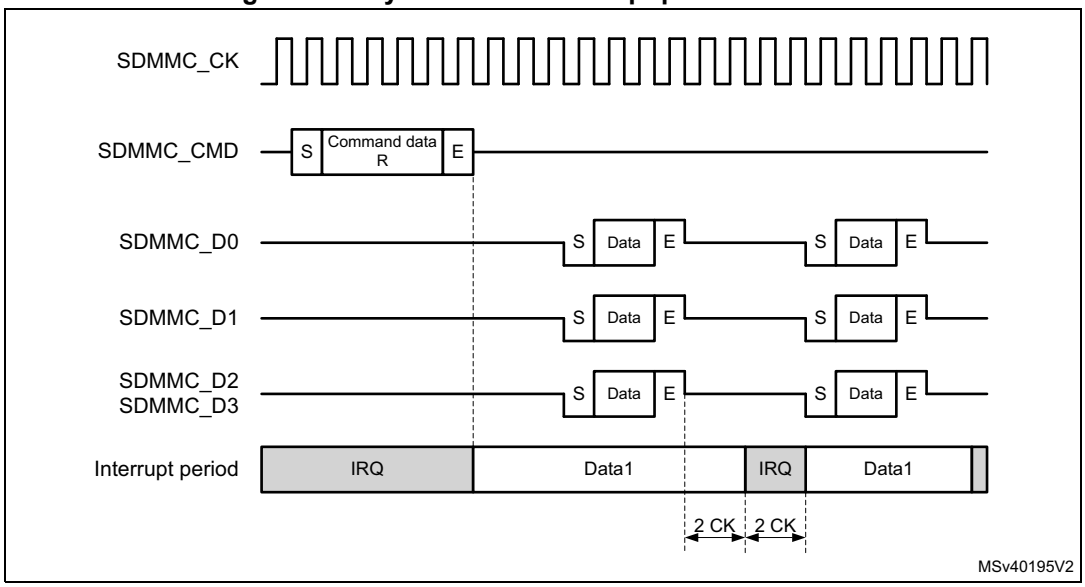
The timing of the interrupt period is depending on the bus speed mode.

In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock.

- The interrupt period ends at the next clock from the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

Note: DTEN must not be used to start data transfer with SD and e•MMC cards.

Figure 101. Synchronous interrupt period data read



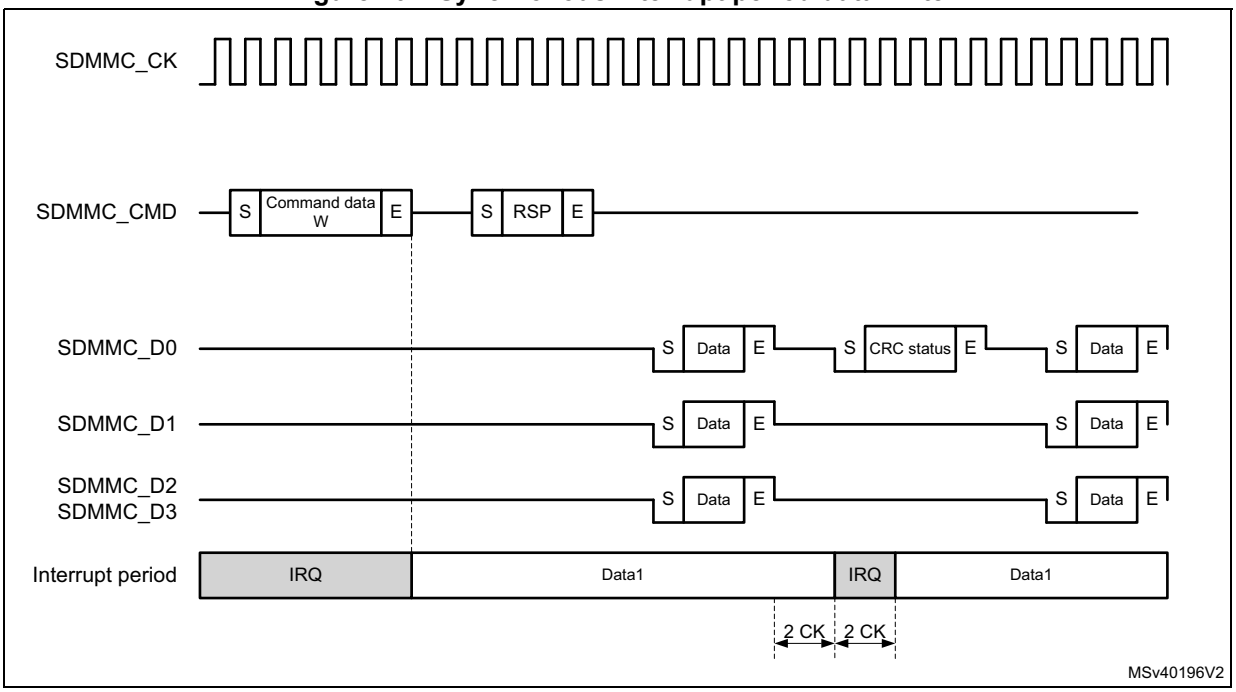


Figure 102. Synchronous interrupt period data write

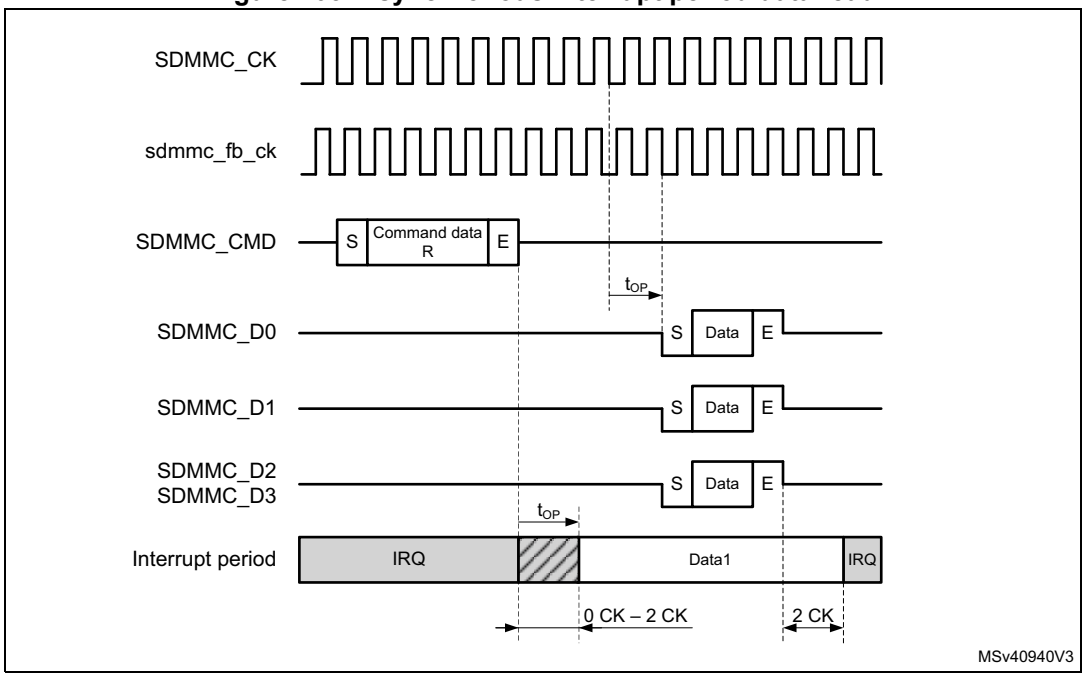
In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the end bit of a command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command end bit are not detected by the host during this interrupt period.
- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host resumes the interrupt period always 2 cycles after the last data block.
- There is NO interrupt period at the data block gap.

Note: DTEN must not be used to start data transfer with SD and e•MMC cards.

Figure 103. Asynchronous interrupt period data read



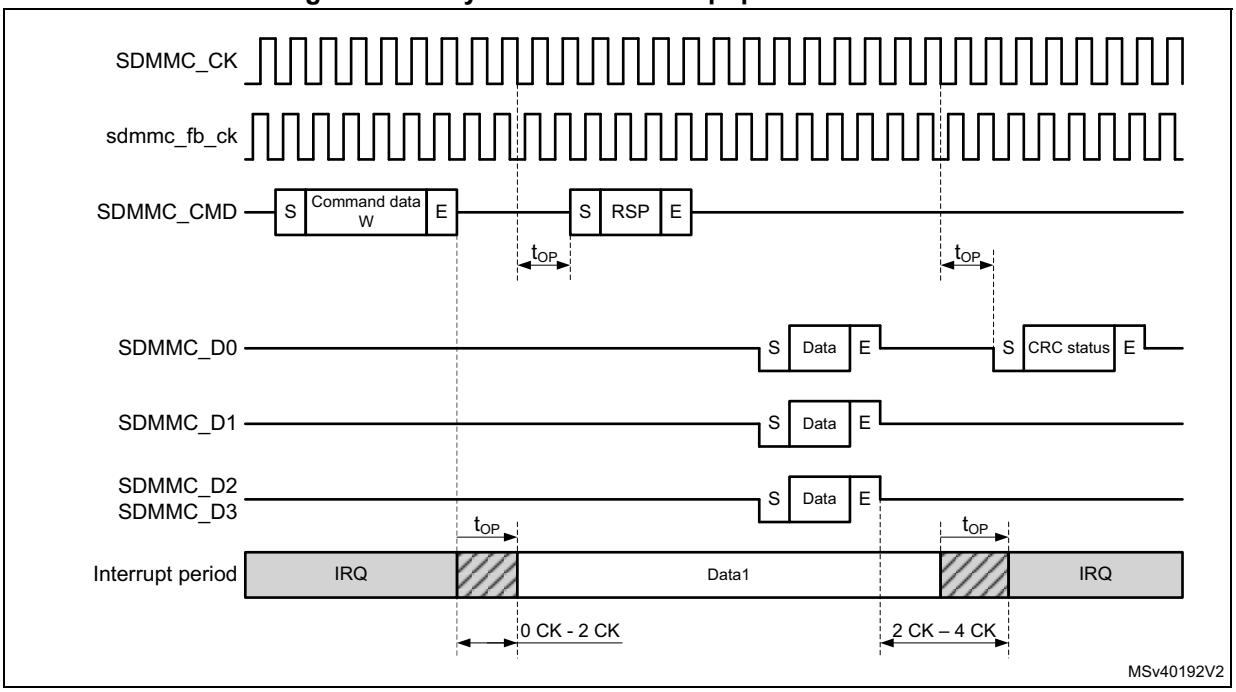


Figure 104. Asynchronous interrupt period data write

When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC masks the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.

In 4-bit mode interrupts can be differentiated from other signaling according *Table 166*.

Table 166. 4-bit mode Start, interrupt, and CRC-status Signaling detection

SDMMC data line	Start	Interrupt	CRC-status
SDMMC_D0	0	1 or CRC-status	0
SDMMC_D1	0	0	X
SDMMC_D2	0	1 or Read Wait	X
SDMMC_D3	0	1	X

SD I/O suspend and resume

This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the *e*•MMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:

1. Determines the function currently using the SDMMC_D[3:0] line(s).
2. Requests the lower-priority or slower transaction to suspend.
3. Waits for the transaction suspension to complete.
4. Begins the higher-priority transaction.
5. Waits for the completion of the higher priority transaction.
6. Restores the suspended transaction.

The card receiving a suspend command responds with its current bus status. Only when the bus has been suspended by the card the bus status indicates suspension completed.

There are different suspend cases conditions:

- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transfered at the same time), the host keeps checking the request until it is accepted (data transfer has suspended).
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during Read Wait.

For the host to know if the bus has been released it must check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation must be saved where after an other operation can start.

The suspend command must be sent with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

The hardware does not save the number of remaining data to be transfered when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps must be taken by firmware:

1. The normal receive process must be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO must be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO must be reset with FIFORST.
2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation must be determined from the remaining number of bytes indicated by the DATACOUNT.

Note: When a DTIMEOUT flag occurs during the suspend procedure, this must be ignored.

To resume receiving data from the card, the following steps must be taken by firmware:

1. The remaining number of data bytes (multiple of data blocks) must be programmed in DATALENGTH.
2. The DPSM must be configured to receive data in the DTDIR bit.
3. The resume command must be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which ends the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card resumes sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps must be taken by firmware:

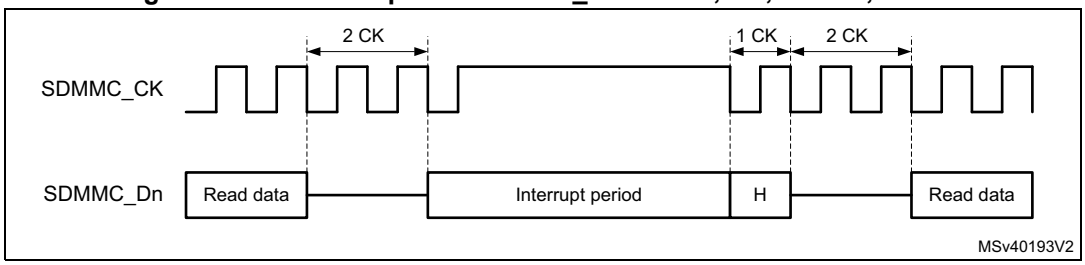
1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)
2. The DPSM must be prevented from start sending a new data block by setting DTHOLD.
3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO must be reset with FIFORST. Any bytes still in the FIFO need to be rewritten when resuming the operation.
4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming must be determined from the remaining number of bytes indicated by the DATACOUNT.
5. To suspend the card the suspend command must be sent by the CPSM with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps must be taken by firmware:

1. The remaining number of data bytes must be programmed in DATALENGTH.
2. The DPSM must be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This ends the interrupt period and start the data transfer. The DPSM either goes to the Wait_S state when SDMMC_D0 does not signal busy, or goes to the Busy state when busy is signaled.
3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transfered.
4. When IDMAEN = 0: Firmware must start filling the FIFO with the remaining data.

SD I/O Read Wait

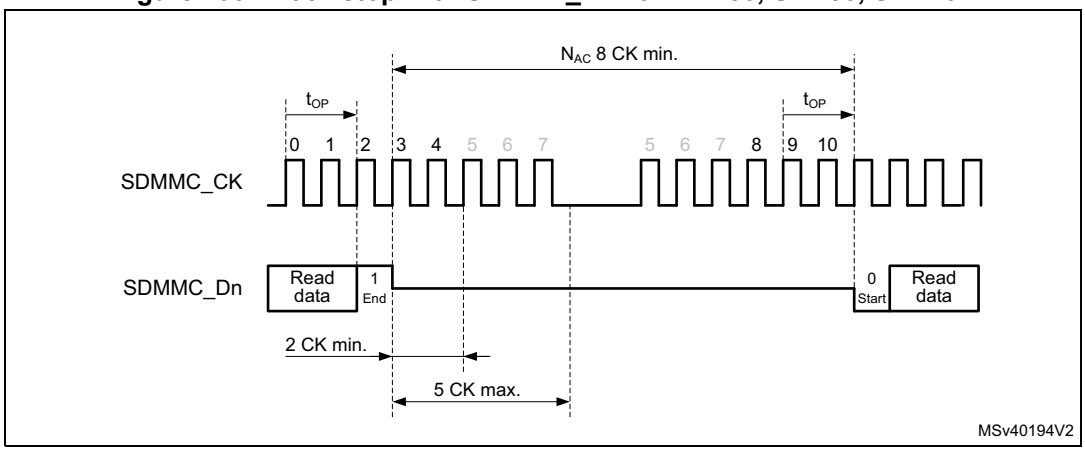
There are two methods to pause the data transfer during the block gap:



1. Stopping the SDMMC_CK.
2. Using Read Wait signaling on SDMMC_D2.

The SDMMC can perform a Read Wait with register settings according *Table 165*.

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

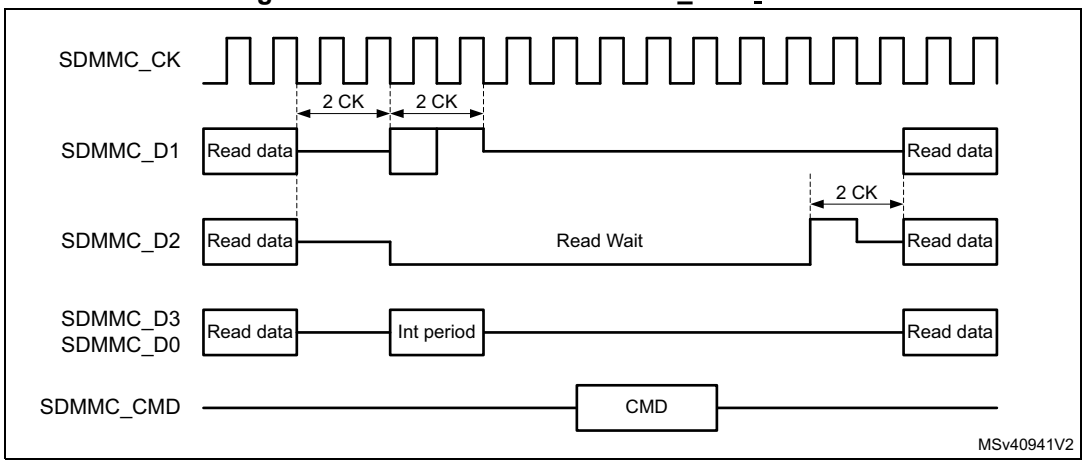


The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the end bit. When ready the host resumes by restarting clock (see *Figure 105*).

Figure 105. Clock stop with SDMMC_CK for DS, HS, SDR12, SDR25

The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see *Figure 106*. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

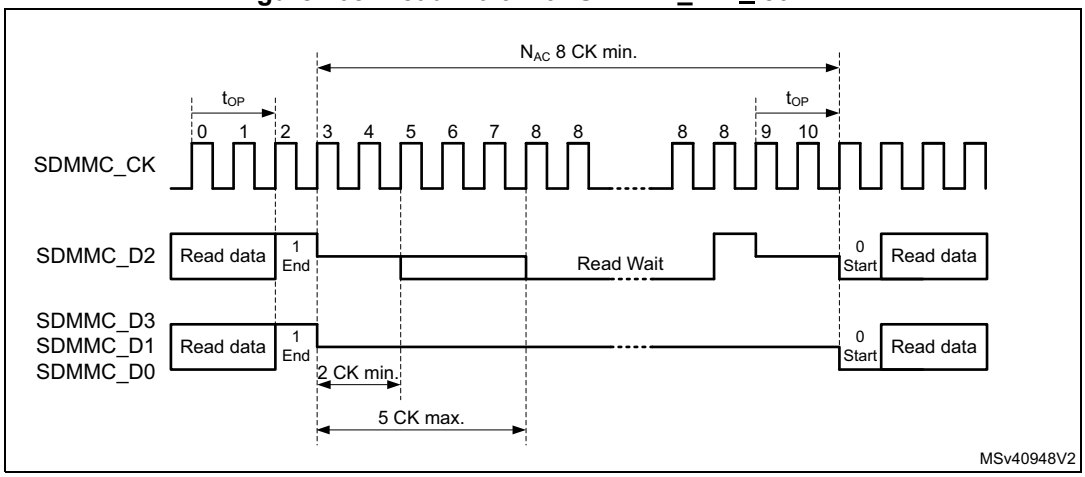
Figure 106. Clock stop with SDMMC_CK for DDR50, SDR50, SDR104



In Read Wait SDMMC_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional Read Wait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.



The timing for Read Wait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see *Figure 107*.

Figure 107. Read Wait with SDMMC_CK < 50 MHz

For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host must raise SDMMC_D2 on the SDMMC_CK clock (see *Figure 108*).

Figure 108. Read Wait with SDMMC_CK ≥ 50 MHz

In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

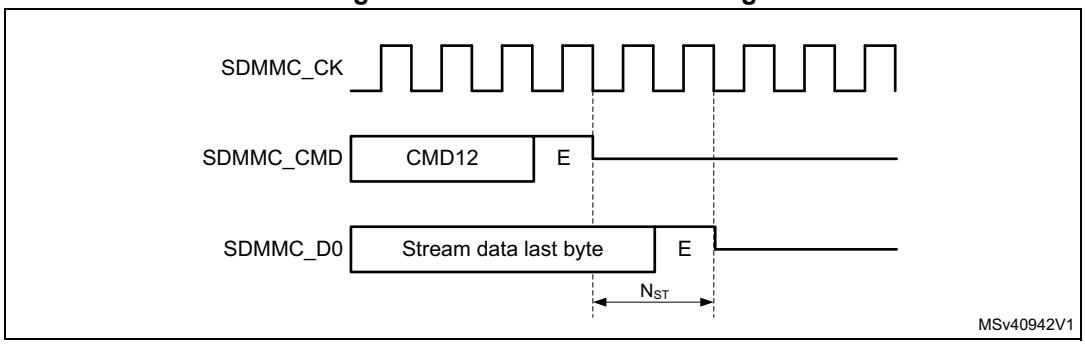
20.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.

Table 167. CMD12 use cases

Data operation	Stop Transmission command CMD12 Description
SDMMC stream write	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block write	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block write with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC stream read	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block read	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block read with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block read. (sending the Stop Transmission command after the card has transmitted the last block is regarded as an illegal command.) Transaction can be aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.

All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:



1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   – This causes the CPSM Abort signal to be generated when the command is sent to the DPSM.
2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   – The card, when sending data, stops data transfer 2 cycles after the Stop Transmission command end bit.
   The card when no data is being sent, does not start sending any new data.
   – The host, when sending data, sends one last data bit followed by an end bit after the Stop Transmission command end bit.
   The host when not sending data, does not start sending any new data.
3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   – When writing data to the card. On the CMDREND flag, firmware must stop writing data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes the FIFO.
   – When reading data from the card. On the CMDREND flag, firmware must read the remaining data from the FIFO. Subsequently the FIFO must be reset with FIFORST.
4. When IDMAEN = 1, hardware takes care of the FIFO.
   – When writing data to the card. On the CPSM Abort signal, hardware stops the IDMA and subsequently the FIFO is flushed.
   – When reading data from the card. On the CPSM Abort signal, hardware instructs the IDMA to transfer the remaining data from the FIFO to RAM.
5. When the FIFO is empty/reset the DABORT flag is generated.

Stream operation and CMD12

To stop the stream transfer after the last byte to be transfered, the CMD12 end bit timing must be sent aligned with the data stream end of last byte. The following write stream data procedure applies:

1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1) end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data end bit and command end bit are aligned.
   – When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be aligned with the data transfer end bit.
   – When DATALENGHT < 5 bytes, Command CMD12 is started before and the DPSM remains in the Wait_S state to align the data transfer end with the CMD12 end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This causes the Preloaded CMD12 to be sent immediately and stop the write data stream.

Figure 109. CMD12 stream timing

To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:

1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   – The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   – CMD12 stops the card sending data.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

Block operation and CMD12

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   – The DPSM does not send more data than indicated by DATALENGTH.
3. Send CMD12 by the CPSM.
   – CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   – The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   – CMD12 stops the Card sending more data and set the card to Idle mode. Any ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

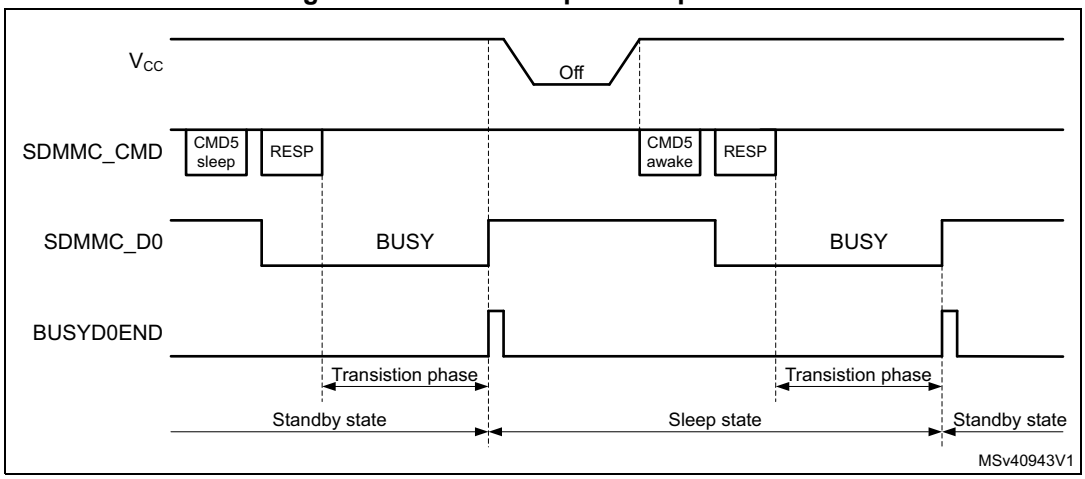
20.6.3 Sleep (CMD5)

The *e*•MMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state.
4. Vcc power supply can be switched off.



The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.

Figure 110. CMD5 Sleep Awake procedure

20.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):

- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):

- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:

1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.
2. Load CMD40 (GO_IRQ_STATE) in the command registers.
3. Enable wait for interrupt by setting WAITINT register bit.
4. Configure the CPSM to send a command immediately.
   – This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for a interrupt service request response.
5. To exit the wait for interrupt state (CPSM Wait state):
   – Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   – To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

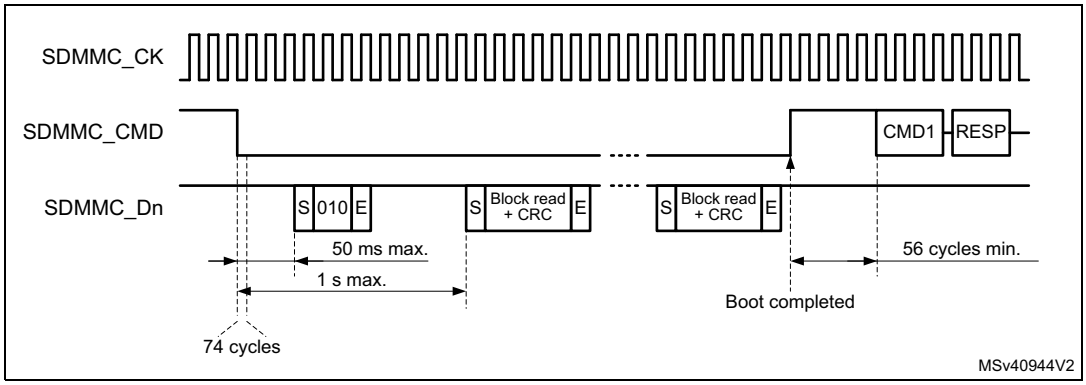
Note: On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

20.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the two boot operation functions:

- Normal boot. (keeping CMD line low)
- Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:



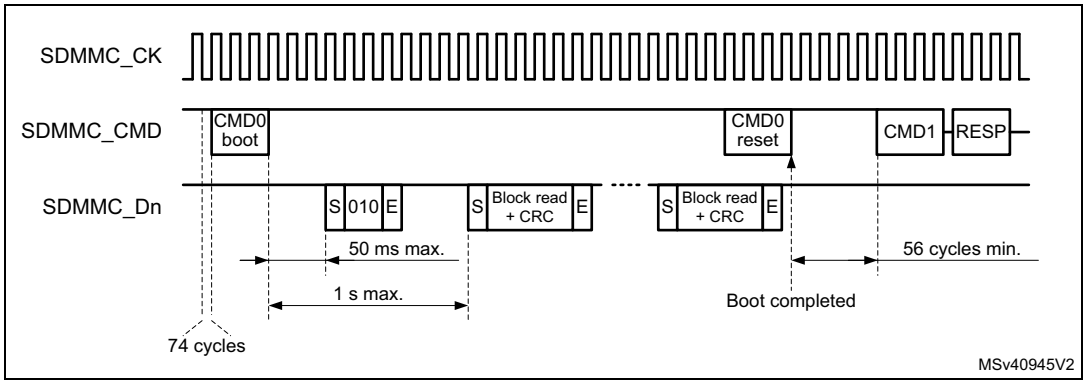
- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to sent the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.

Figure 111. Normal boot mode operation



To perform the normal boot procedure the following steps needed:

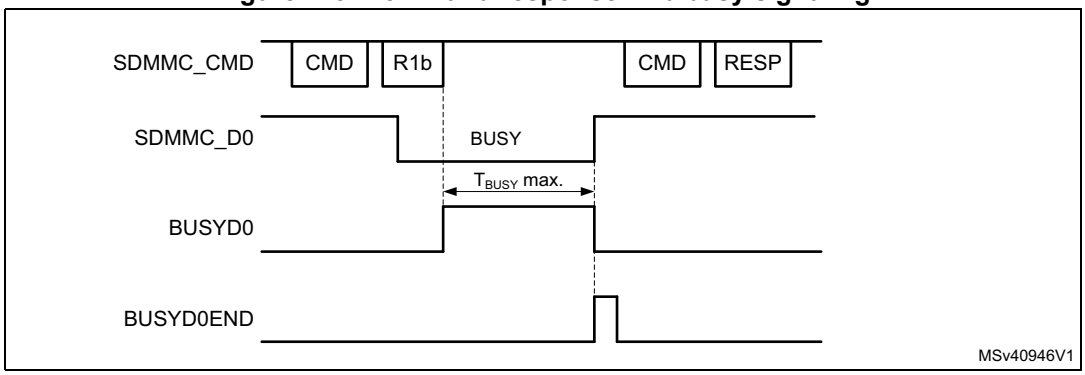
1. Reset the card.
2. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN.This causes:
   – the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   – the ACK timeout to start.
   – DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   – when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   – when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. when all boot data has been received the DATAEND flag occurs.
   – when data CRC fails the DCRCFAIL flag is also generated.
   – when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   – If the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.

Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 112. Alternative boot mode operation

To perform the alternative boot procedure the following steps needed:



1. Move the SDMMC to power-off state, and reset the card.
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of boot command confirmation, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
   - the loaded command and argument to be sent out. (BOOTMODE = alternative boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when enabled.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
8. when all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.

9. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to occur 56 cycles after the Command.
   – if the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops the data transfer and disable the DPSM which triggers an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command. When the RESET command has been sent successfully, the BOOTMODE control bit has to be cleared to terminate the boot operation.

20.6.6 Response R1b handling

When sending commands which have a R1b response the busy signaling is reflected in the BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the same time the BUSYD0END flag is generated.

Figure 113. Command response R1b busy signaling

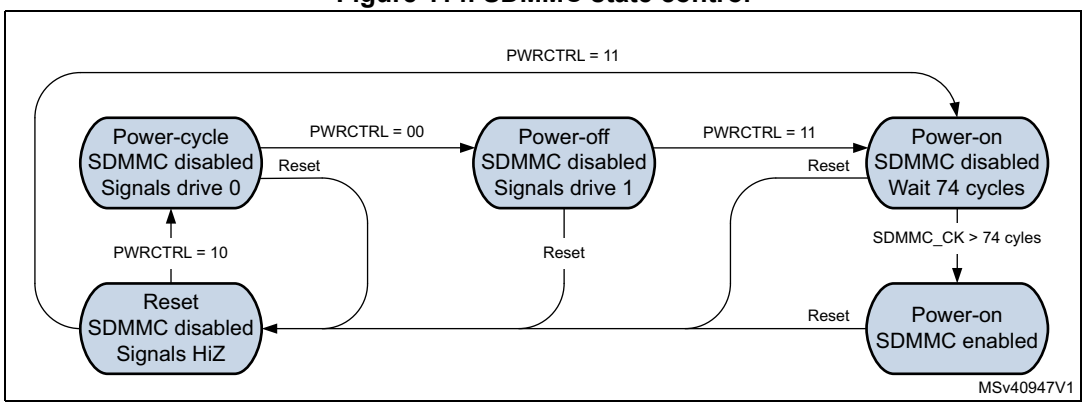
The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:

- Enable CMDREND flag.
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  – If BUSYD0 signals not busy, signal busy release to firmware
  – If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

20.6.7 Reset and card cycle power

Reset



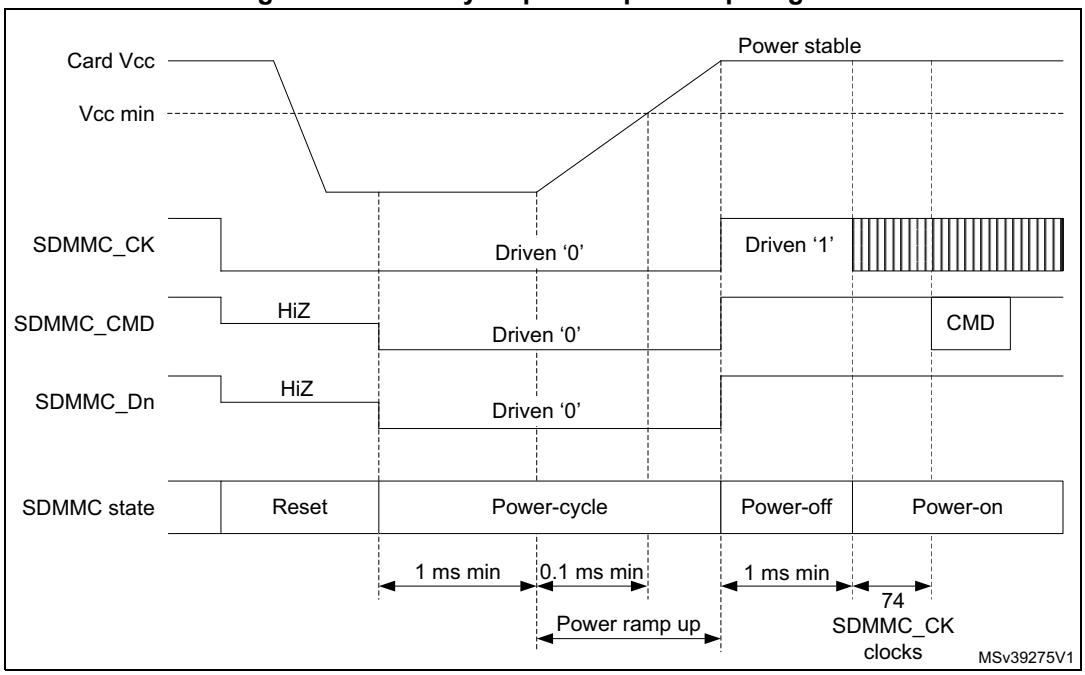
Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command nor data can be transfered. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transfered.

The SDMMC states are controlled by Firmware with the PWRCTL register bits according *Figure 114.*.

Figure 114. SDMMC state control



Card cycle power

To perform a card cycle power the following procedure applies:

1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1 ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive 1.
6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

Figure 115. Card cycle power / power up diagram

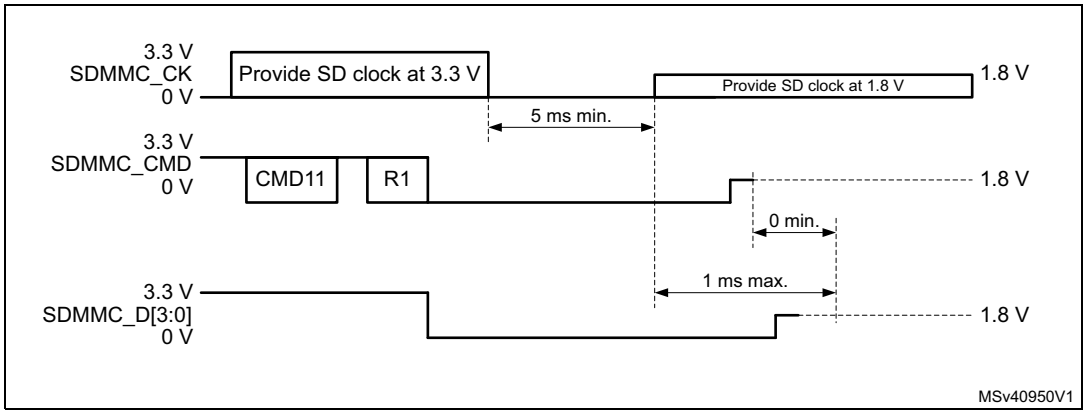
20.7 Hardware flow control

The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see *Section : IDMA transfer error management*).

To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.



Hardware flow control must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a t_{OP} and Dt_{OP} delay > 1 cycle, hardware flow control can not be used.

20.8 Ultra-high-speed phase I (UHS-I) voltage switch

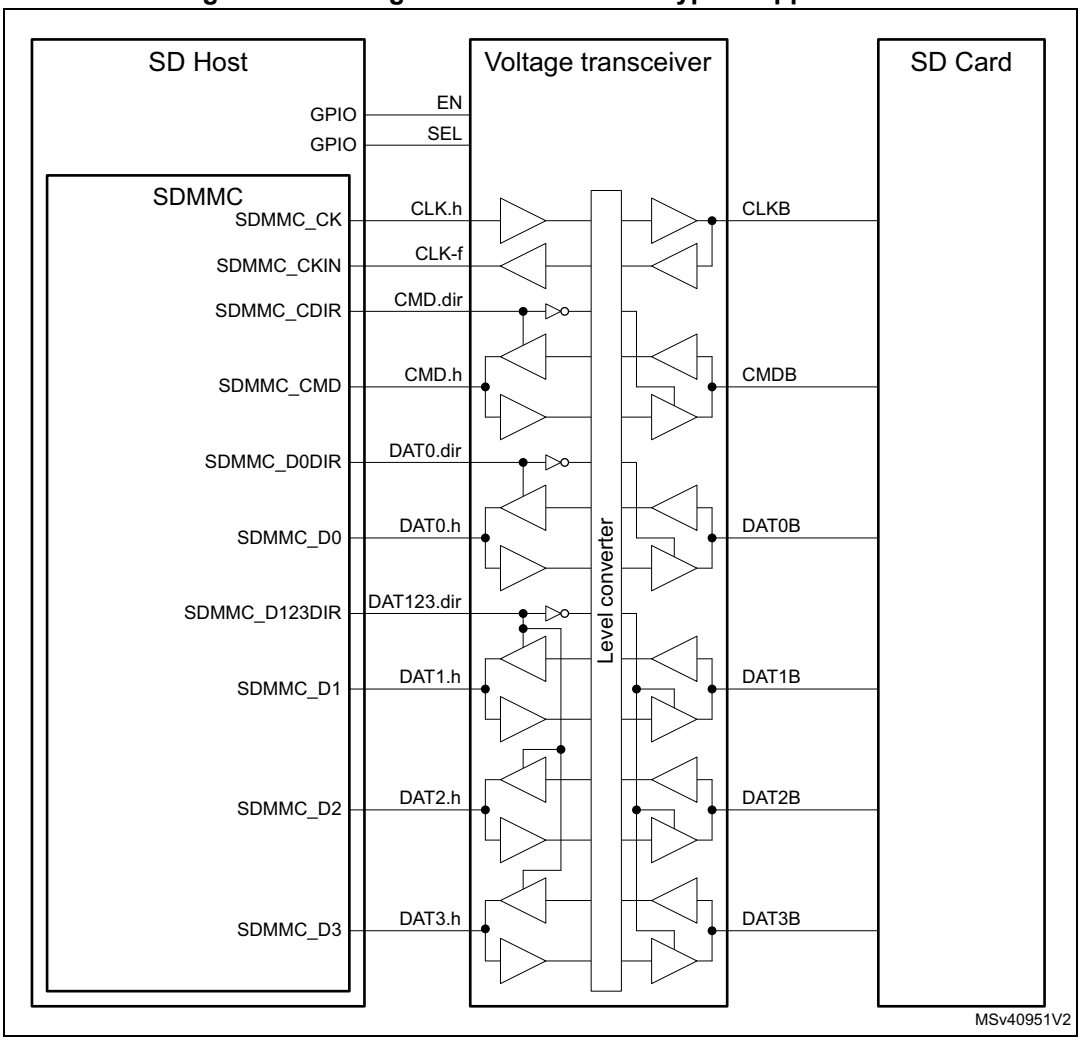
UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8 V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch

sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

Figure 116. CMD11 signal voltage switch sequence

To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.
   - When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.
6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.
7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.
8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].
9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.



10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:
    – When BUSYD0 is detected high, Voltage Switch has been completed successfully.
    – When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by 2^{12} cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by 2^9 cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.

Figure 117. Voltage switch transceiver typical application

To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

- **SDMMC_CKIN** feedback input clock
- **SDMMC_CDIR** I/O direction control for the CMD signal
- **SDMMC_D0DIR** I/O direction control for the SDMMC_D0 signal
- **SDMMC_D123DIR** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMC_POWER.DIRPOL control bit.

20.9 SDMMC interrupts

Table 168. SDMMC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode
SDMMC	Command response CRC fail	CCRCFAIL	CCRCFAILIE	CCRCFAILC	Yes
SDMMC	Data block CRC fail	DCRCFAIL	DCRCFAILIE	DCRCFAILC	Yes
SDMMC	Command response timeout	CTIMEOUT	CTIMEOUTIE	CTIMEOUTC	Yes
SDMMC	Data timeout	DTIMEOUT	DTIMEOUTIE	DTIMEOUTC	Yes

SDMMC	IDMA transfer error	IDMATE	IDMATEIE	IDMATEC	Yes
SDMMC	IDMA buffer transfer complete	IDMABTC	IDMABTCIE	IDMABTCC	Yes

20.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and half-word (16-bit) accesses trigger an AHB bus error.

20.10.1 SDMMC power control register (SDMMC_POWER)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIR POL	VSWI TCHEN	VSWI TCH	PWRCTRL[1:0]	
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DIRPOL**: Data and command direction signals polarity selection

This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).

0: Voltage transceiver I/Os driven as output when direction signal is low.

1: Voltage transceiver I/Os driven as output when direction signal is high.

Bit 3 **VSWITCHEN**: Voltage switch procedure enable

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

This bit is used to stop the SDMMC_CK after the voltage switch command response:

0: SDMMC_CK clock kept unchanged after successfully received command response.

1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 **VSWITCH**: Voltage switch sequence start

This bit is used to start the timing critical section of the voltage switch sequence:

0: Voltage switch sequence not started and not active.

1: Voltage switch sequence started or active.

Bits 1:0 **PWRCTRL[1:0]**: SDMMC state control bits

These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).

These bits are used to define the functional state of the SDMMC signals:

00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.

01: Reserved (When written 01, PWRCTRL value does not change)

10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.

11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation.

Any further write is ignored, PWRCTRL value keeps 11.

20.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SELCLKRX[1:0]		BUS SPEED	DDR	HWFC_EN	NEG EDGE
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WID BUS[1:0]		Res.	PWR SAV	Res.	Res.	CLKDIV[9:0]									
rw	rw		rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **SELCLKRX[1:0]**: Receive clock selection

These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: sdmmc_io_in_ck selected as receive clock

01: SDMMC_CKIN feedback clock selected as receive clock

10: sdmmc_fb_ck tuned feedback clock selected as receive clock

11: Reserved (select sdmmc_io_in_ck)

Bit 19 **BUSSPEED**: Bus speed for selection of SDMMC operating modes

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected

1: SDR50, DDR50, SDR104, HS200 bus speed mode selected

Bit 18 **DDR**: Data rate signaling selection

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus).

DDR rate must only be selected with clock division > 1 (CLKDIV > 0).

0: SDR Single data rate signaling

1: DDR double data rate signaling

Bit 17 **HWFC_EN**: Hardware flow control enable

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: Hardware flow control is disabled

1: Hardware flow control is enabled

When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in *Section 20.10.11*.

Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.

0: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- Data changed on the sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

1: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.
- Data changed on the SDMMC_CK falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)

01: 4-bit wide bus mode: SDMMC_D[3:0] used

10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:

0: SDMMC_CK clock is always enabled

1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

This field defines the divide factor between the input clock (sdmmc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmc_ker_ck / [2 * CLKDIV].

0x000: SDMMC_CK frequency = sdmmc_ker_ck / 1 (Does not support DDR)

0x001: SDMMC_CK frequency = sdmmc_ker_ck / 2

0x002: SDMMC_CK frequency = sdmmc_ker_ck / 4

0x0XX: ..

0x080: SDMMC_CK frequency = sdmmc_ker_ck / 256

0xXXX: ..

0x3FF: SDMMC_CK frequency = sdmmc_ker_ck / 2046

Note: While the SD/SDIO card or e•MMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.

The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.

At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

20.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008

Reset value: 0x0000 0000

This register contains a 32-bit command argument, which is sent to a card as part of a command message.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDARG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDARG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CMDARG[31:0]**: Command argument

These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

20.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMD SUS PEND
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT EN	BOOT MODE	DT HOLD	CPSM EN	WAITP END	WAIT INT	WAITRESP[1:0]		CMD STOP	CMD TRANS	CMDINDEX[5:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS = 0.
CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF = 1.

Bit 15 **BOOTEN**: Enable boot mode procedure

0: Boot mode procedure disabled
1: Boot mode procedure enabled

Bit 14 **BOOTMODE**: Select the boot mode procedure to be used

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
0: Normal boot mode procedure selected
1: Alternative boot mode procedure selected

Bit 13 **DTHOLD**: Hold new data block transmission and reception in the DPSM

If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12 **CPSMEN**: Command path state machine (CPSM) enable bit

This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
If this bit is set, the CPSM is enabled.
When DTEN = 1, no command is transfered nor boot procedure is started. CPSMEN is cleared to 0.
During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11 **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM

This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
WAITPEND is only taken into account when DTMODE = *e*•MMC stream data transfer, WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8 **WAITRESP[1:0]**: Wait for response bits

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
00: No response, expect CMDSENT flag
01: Short response, expect CMDREND or CCRCFAIL flag
10: Short response, expect CMDREND flag (No CRC)
11: Long response, expect CMDREND or CCRCFAIL flag

Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 **CMDINDEX[5:0]**: Command index

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

The command index is sent to the card as part of a command message.

Note: 1 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2 MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses,136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

20.10.5 SDMMC command response register (SDMMC_RESPCMDR)

Address offset: 0x010

Reset value: 0x0000 0000

This register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESPCMD[5:0]					
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index

Read-only bitfield. Contains the command index of the last command response received.

20.10.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)

Reset value: 0x0000 0000

These registers contain the status of a card, which is part of the received response.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CARDSTATUS[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CARDSTATUS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CARDSTATUS[31:0]**: Card status according table below
See *Table 169*.

The card status size is 32 or 128 bits, depending on the response type.

Table 169. Response type and SDMMC_RESPxR registers

Register(1)	Short response	Long response
SDMMC_RESP1R	Card status[31:0]	Card status [127:96]
SDMMC_RESP2R	all 0	Card status [95:64]
SDMMC_RESP3R	all 0	Card status [63:32]
SDMMC_RESP4R	all 0	Card status [31:0](2)

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

20.10.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024

Reset value: 0x0000 0000

This register contains the data timeout period, in card bus clock periods.

A counter loads the value from this register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATATIME[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATATIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATATIME[31:0]**: Data and R1b busy timeout period

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

Data and R1b busy timeout period expressed in card bus clock periods.

Note: A data transfer must be written to the data timer register and the data length register before being written to the data control register.

20.10.8 SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

This register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATALENGTH[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATALENGTH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATALENGTH[24:0]**: Data length value

This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Number of data bytes to be transferred.

When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not transfered)

When DATALENGTH = 0 no data are transfered, when requested by a CPSMEN and CMDTRANS = 1 also no command is transfered. DTEN and CPSMEN are cleared to 0.

Note: For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.

20.10.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C

Reset value: 0x0000 0000

This register controls the data path state machine (DPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FIFO RST	BOOT ACK EN	SDIO EN	RW MOD	RW STOP	RW START	DBLOCKSIZE[3:0]				DTMODE[1:0]		DTDIR	DTEN
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **FIFORST**: FIFO reset, flushes any remaining data

This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSMACT = 1). This bit only takes effect when a transfer error or transfer hold occurs.

0: FIFO not affected.

1: Flush any remaining data and reset the FIFO pointers. This bit is automatically cleared to 0 by hardware when DPSM gets inactive (DPSMACT = 0).

Bit 12 **BOOTACKEN**: Enable the reception of the boot acknowledgment

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Boot acknowledgment disabled, not expected to be received

1: Boot acknowledgment enabled, expected to be received

Bit 11 **SDIOEN**: SD I/O interrupt enable functions

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

If this bit is set, the DPSM enables the SD I/O card specific interrupt operation.

Bit 10 **RWMOD**: Read Wait mode

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Read Wait control using SDMMC_D2

1: Read Wait control stopping SDMMC_CK

Bit 9 **RWSTOP**: Read Wait stop

This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or Idle state.

0: No Read Wait stop

1: Enable for Read Wait stop when DPSM is in the R_W state.

Bit 8 **RWSTART**: Read Wait start

If this bit is set, Read Wait operation starts.

Bits 7:4 **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Define the data block length when the block data transfer mode is selected:

0000: Block length = 2^0 = 1 byte

0001: Block length = 2^1 = 2 bytes

0010: Block length = 2^2 = 4 bytes

0011: Block length = 2^3 = 8 bytes

0100: Block length = 2^4 = 16 bytes

0101: Block length = 2^5 = 32 bytes

0110: Block length = 2^6 = 64 bytes

0111: Block length = 2^7 = 128 bytes

1000: Block length = 2^8 = 256 bytes

1001: Block length = 2^9 = 512 bytes

1010: Block length = 2^{10} = 1024 bytes

1011: Block length = 2^{11} = 2048 bytes

1100: Block length = 2^{12} = 4096 bytes

1101: Block length = 2^{13} = 8192 bytes

1110: Block length = 2^{14} = 16384 bytes

1111: Reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transfered data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transfered.)

When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transfered)

Bits 3:2 **DTMODE[1:0]**: Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

00: Block data transfer ending on block count.

01: SDIO multibyte data transfer.

10: *e*•MMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)

11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1 **DTDIR**: Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: From host to card.

1: From card to host.

Bit 0 **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by hardware when data transfer completes.

This bit must only be used to transfer data when no associated data transfer command is used (must not be used with SD or *e*•MMC cards).

0: Do not start data transfer without CPSM data transfer command.

1: Start data transfer without CPSM data transfer command.

20.10.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

This register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then moves to the Idle state and

when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATACOUNT[24:16]								
							r	r	r	r	r	r	r	r	r

DATACOUNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value

When read, the number of remaining data bytes to be transferred is returned. Write has no effect.

Note: This register must be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transfered.

20.10.11 SDMMC status register (SDMMC_STAR)

Address offset: 0x034

Reset value: 0x0000 0000

This register is a read-only register. It contains two types of flag:

- Static flags (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- Dynamic flags (bits [20:12]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTC**: IDMA buffer transfer complete

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 27 **IDMATE**: IDMA transfer error

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 26 **CKSTOP**: SDMMC_CK stopped in Voltage switch procedure

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 25 **VSWEND**: Voltage switch critical timing section completion
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOIT**: SDIO interrupt received
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected
This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.
1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response
This bit is reset to not busy when the SDMMCD0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.
0: card signals not busy on SDMMC_D0.
1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty
This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full
This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full
There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty
At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full.

Bit 13 **CPSMACT**: Command path state machine active (not in Idle state)
This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPSMACT**: Data path state machine active (not in Idle state)
This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the R_W state
or
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to Wait_S.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHOLD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Note: FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.

20.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038

Reset value: 0x0000 0000

This register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 23 **ACKFAILC**: ACKFAIL flag clear bit
Set by software to clear the ACKFAIL flag.
0: ACKFAIL not cleared
1: ACKFAIL cleared

Bit 22 **SDIOITC**: SDIOIT flag clear bit
Set by software to clear the SDIOIT flag.
0: SDIOIT not cleared
1: SDIOIT cleared

Bit 21 **BUSYD0ENDC**: BUSYD0END flag clear bit
Set by software to clear the BUSYD0END flag.
0: BUSYD0END not cleared
1: BUSYD0END cleared

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **DABORTC**: DABORT flag clear bit
Set by software to clear the DABORT flag.
0: DABORT not cleared
1: DABORT cleared

Bit 10 **DBCKENDC**: DBCKEND flag clear bit
Set by software to clear the DBCKEND flag.
0: DBCKEND not cleared
1: DBCKEND cleared

Bit 9 **DHOLDC**: DHOLD flag clear bit
Set by software to clear the DHOLD flag.
0: DHOLD not cleared
1: DHOLD cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit
Set by software to clear the DATAEND flag.
0: DATAEND not cleared
1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit
Set by software to clear the CMDSENT flag.
0: CMDSENT not cleared
1: CMDSENT cleared

Bit 6 **CMDRENDC**: CMDREND flag clear bit
Set by software to clear the CMDREND flag.
0: CMDREND not cleared
1: CMDREND cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit
Set by software to clear the RXOVERR flag.
0: RXOVERR not cleared
1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit
Set by software to clear TXUNDERR flag.
0: TXUNDERR not cleared
1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
Set by software to clear the DTIMEOUT flag.
0: DTIMEOUT not cleared
1: DTIMEOUT cleared

Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit
Set by software to clear the CTIMEOUT flag.
0: CTIMEOUT not cleared
1: CTIMEOUT cleared

Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit
Set by software to clear the DCRCFAIL flag.
0: DCRCFAIL not cleared
1: DCRCFAIL cleared

Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit
Set by software to clear the CCRCFAIL flag.
0: CCRCFAIL not cleared
1: CCRCFAIL cleared

20.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCIE**: IDMA buffer transfer complete interrupt enable
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
0: IDMA buffer transfer complete interrupt disabled
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CKSTOPIE**: Voltage switch clock stopped interrupt enable
Set and cleared by software to enable/disable interrupt caused by voltage switch clock stopped.
0: Voltage switch clock stopped interrupt disabled
1: Voltage switch clock stopped interrupt enabled

Bit 25 **VSWENDIE**: Voltage switch critical timing section completion interrupt enable
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
0: Voltage switch critical timing section completion interrupt disabled
1: Voltage switch critical timing section completion interrupt enabled

Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFAILIE**: Acknowledgment fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment fail.
0: Acknowledgment fail interrupt disabled
1: Acknowledgment fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO mode interrupt received interrupt disabled
1: SDIO mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled

Bit 9 **DHOLDIE**: Data hold interrupt enable
Set and cleared by software to enable/disable the interrupt generated when sending new data is hold in the DPSM Wait_S state.
0: Data hold interrupt disabled
1: Data hold interrupt enabled

Bit 8 **DATAENDIE**: Data end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data end.
0: Data end interrupt disabled
1: Data end interrupt enabled

Bit 7 **CMDSENTIE**: Command sent interrupt enable
Set and cleared by software to enable/disable interrupt caused by sending command.
0: Command sent interrupt disabled
1: Command sent interrupt enabled

Bit 6 **CMDRENDIE**: Command response received interrupt enable
Set and cleared by software to enable/disable interrupt caused by receiving command response.
0: Command response received interrupt disabled
1: command Response received interrupt enabled

Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.
0: Rx FIFO overrun error interrupt disabled
1: Rx FIFO overrun error interrupt enabled

Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.
0: Tx FIFO underrun error interrupt disabled
1: Tx FIFO underrun error interrupt enabled

Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by data timeout.
0: Data timeout interrupt disabled
1: Data timeout interrupt enabled

Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by command timeout.
0: Command timeout interrupt disabled
1: Command timeout interrupt enabled

Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by data CRC failure.
0: Data CRC fail interrupt disabled
1: Data CRC fail interrupt enabled

Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by command CRC failure.
0: Command CRC fail interrupt disabled
1: Command CRC fail interrupt enabled

20.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040

Reset value: 0x0000 0000

This register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from this register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this states, the acknowledgment timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACKTIME[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACKTIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **ACKTIME[24:0]**: Boot acknowledgment timeout period
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
Boot acknowledgment timeout period expressed in card bus clock periods.

Note: The data transfer must be written to the acknowledgment timer register before being written to the data control register.

20.10.15 SDMMC DMA control register (SDMMC_IDMACTRLR)

Address offset: 0x050

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMAB MODE	IDMA EN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **IDMABMODE**: Buffer mode selection
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: Single buffer mode.
1: Linked list mode.

Bit 0 **IDMAEN**: IDMA enable
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: IDMA disabled
1: IDMA enabled

20.10.16 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER)

Address offset: 0x054

Reset value: 0x0000 0000

This register contains the buffer size when in linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMABNDT[11]
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABNDT[10:0]											Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw					

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:5 **IDMABNDT[11:0]**: Number of bytes per buffer
This 12-bit value must be multiplied by 8 to get the size of the buffer in 32-bit words and by 32 to get the size of the buffer in bytes.
Example: IDMABNDT = 0x001: buffer size = 8 words = 32 bytes.
Example: IDMABNDT = 0x800: buffer size = 16384 words = 64 Kbyte.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 4:0 Reserved, must be kept at reset value.

20.10.17 SDMMC IDMA buffer base address register (SDMMC_IDMABASER)

Address offset: 0x058

Reset value: 0x0000 0000

This register contains the memory buffer base address in single buffer configuration and linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABASE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABASE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r

Bits 31:0 **IDMABASE[31:0]**: Buffer memory base address bits [31:2], must be word aligned (bit [1:0] are always 0 and read only)

This register can be written by firmware when DPSM is inactive (DPSMACT = 0), and can dynamically be written by firmware when DPSM active (DPSMACT = 1).

20.10.18 SDMMC IDMA linked list address register (SDMMC_IDMALAR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ULA	ULS	ABR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMALA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **ULA**: Update SDMMC_IDMALAR from linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMALAR is not to be updated, last linked list item.
1: SDMMC_IDMALAR is to be updated from linked list table.

Bit 30 **ULS**: Update SDMMC_IDMABSIZE from the next linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode and ULA = 1)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMABSIZER is not to be updated from next linked list table.
1: SDMMC_IDMABSIZER is to be updated from next linked list table.

Bit 29 **ABR**: Acknowledge linked list buffer ready
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
This bit is not taken into account when starting the first linked list buffer from the software programmed register information. ABR is only taken into account on subsequent loaded linked list items.
0: Loaded linked list buffer is not ready (this causes a linked list IDMA transfer error to be generated).
1: Loaded linked list buffer ready acknowledge. Linked list buffer data are transfered by IDMA.

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:2 **IDMALA[13:0]**: Word aligned linked list item address offset
Linked list item offset pointer to the base of the next linked list item structure.
Linked list item base address is IDMABA + IDMALA.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

20.10.19 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR)

Address offset: 0x068

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABA[29:14]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:2 **IDMABA[29:0]**: Word aligned Linked list memory base address
Linked list memory base pointer.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

20.10.20 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)

Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FIFODATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FIFODATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data

This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).

The FIFO data occupies 16 entries of 32-bit words.

Refer to *Section 2.3 on page 97* for the register boundary addresses.

21 Delay block (DLYB)

21.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

21.2 DLYB main features

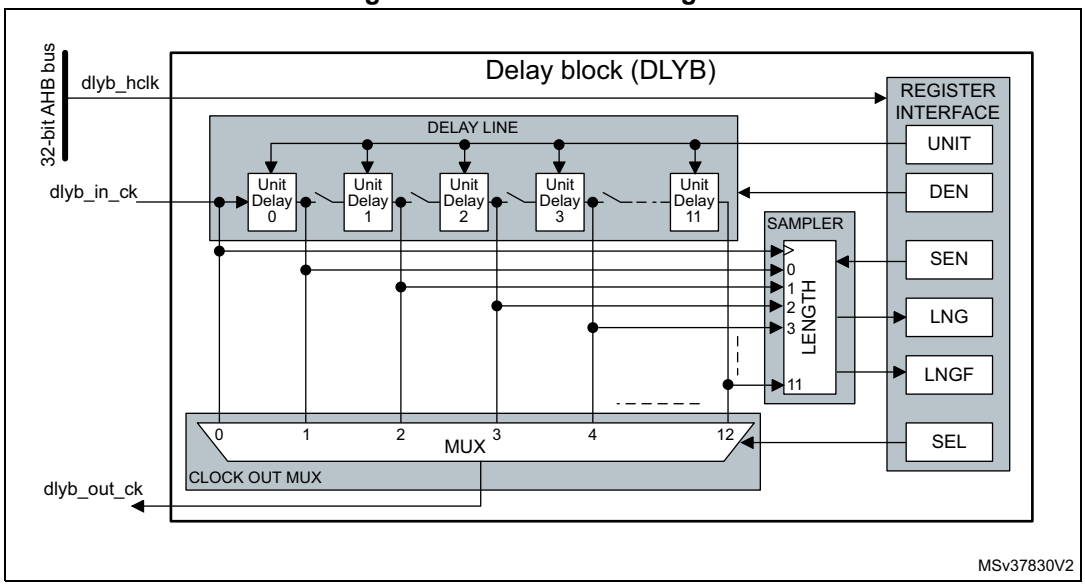
The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

21.3 DLYB implementation

Table 171. STM32U3 series features

DLYB associated peripheral	DLYBOS1	DLYBSD1
OCTOSPI1	X	-
SDMMC1	-	X



21.4 DLYB functional description

21.4.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 118. DLYB block diagram

21.4.2 DLYB pins and internal signals

Table 172 lists the DLYB internal signals.

Table 172. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

21.4.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 173. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don't care	Don't care	Don't care	Don't care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don't care	Don't care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

21.4.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

21.4.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

Octo-SPI use case:

The delay block is used in conjunction with Octo-SPI interface to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain type of devices. Note that in case DQS is used, the calibration procedure must be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user must typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.

In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value must be close to N/4, once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small "Unit" gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

SDMMC use case:

The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

21.5 DLYB registers

All registers can be accessed in word, half-word and byte access.

21.5.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

21.5.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.

These bits can only be written when SEN = 1.

Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.

These bits can only be written when SEN = 1.

Output clock phase = input clock + SEL[3:0] x unit delay

21.5.3 DLYB register map

Table 174. DLYB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

22 Analog-to-digital converters (ADC)

22.1 Introduction

This section describes the implementation of up to 2 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master)

Each ADC consists of one 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 19 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan, or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned (default configuration) 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

22.2 ADC main features

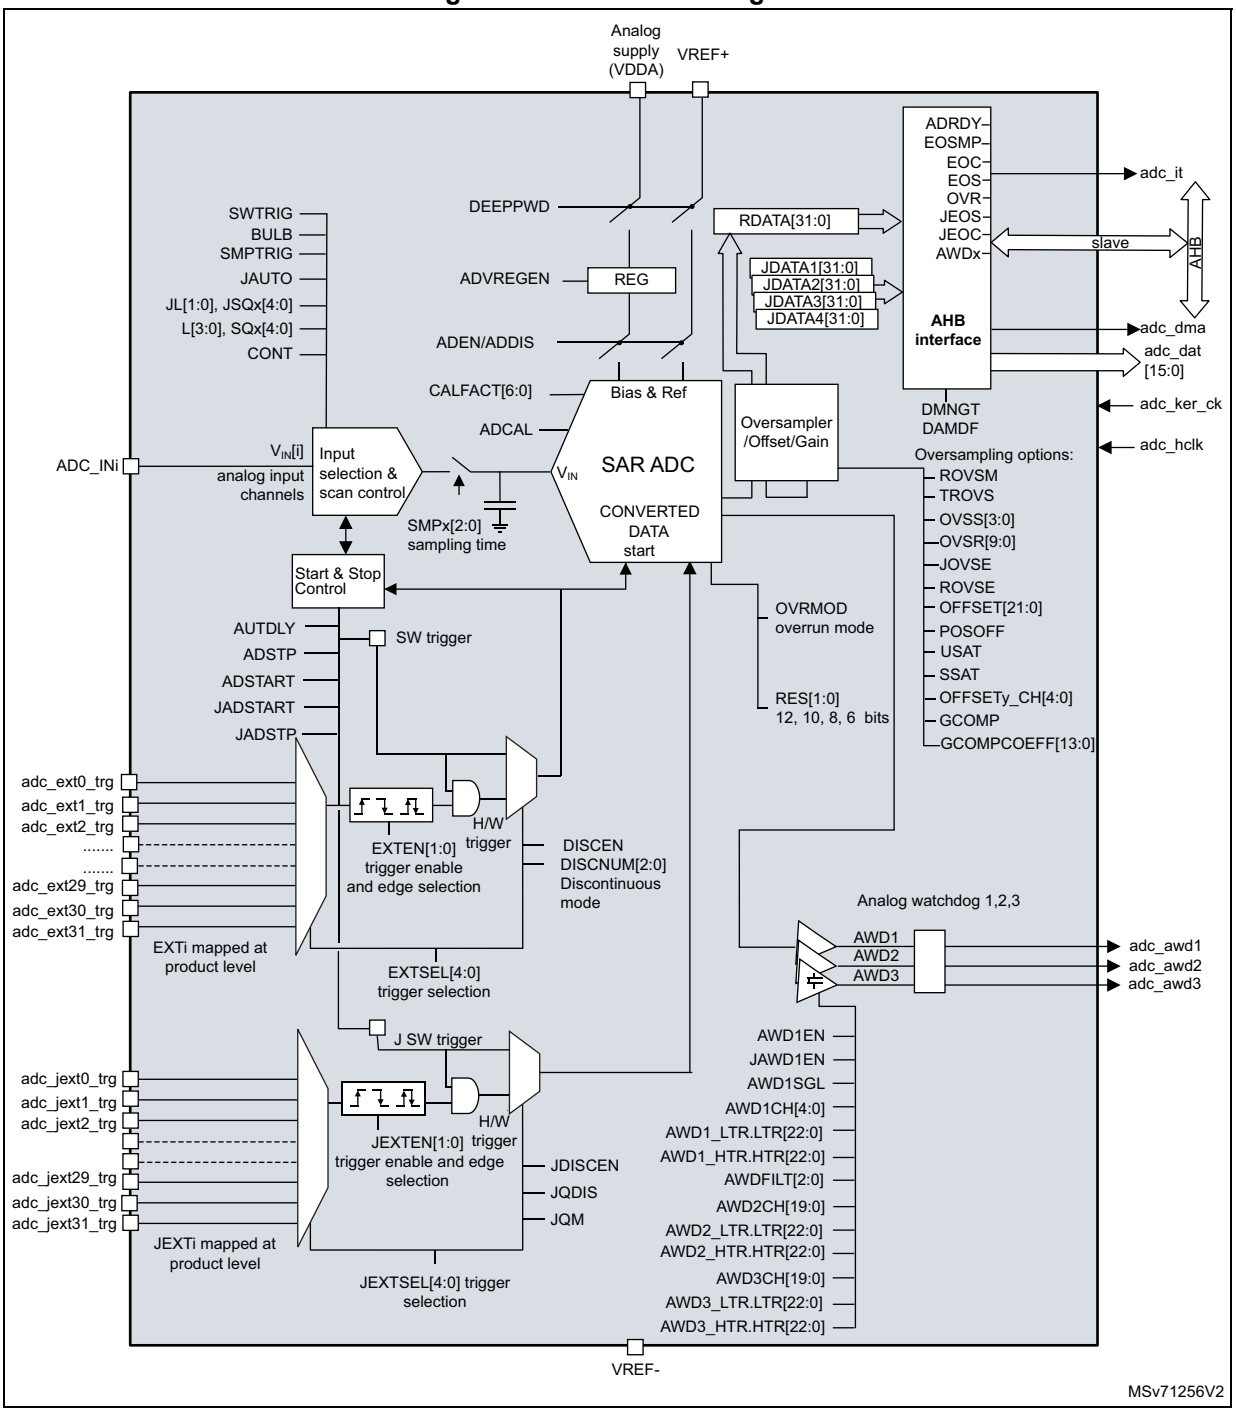
- High-performance features
  - Up to 2 ADCs which can operate in dual mode
    ADC1 is connected to 15 external channels + 4 internal channels
    ADC2 is connected to 13 external channels + 6 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - AHB slave bus interface to allow fast data handling
  - Offset calibration support
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Fixed latency for a trigger to start of sampling
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to ADF for post processing
  - Four dedicated data registers for the injected channels

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (autodelayed mode)
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shifts
- Data preconditioning
  - Gain compensation
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC): up to 15 GPIO pads
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for the internal temperature sensor (V_{SENSE})
  - 1 channel for monitoring the external VBAT power supply pin
  - 1 channel for monitoring V_{CORE} internal voltage
  - Connection to DAC internal channels
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timer events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 119 shows the block diagram of one ADC.

22.3 ADC implementation

Table 175. ADC features



ADC modes/features	ADC1, ADC2
Resolution	12 bits

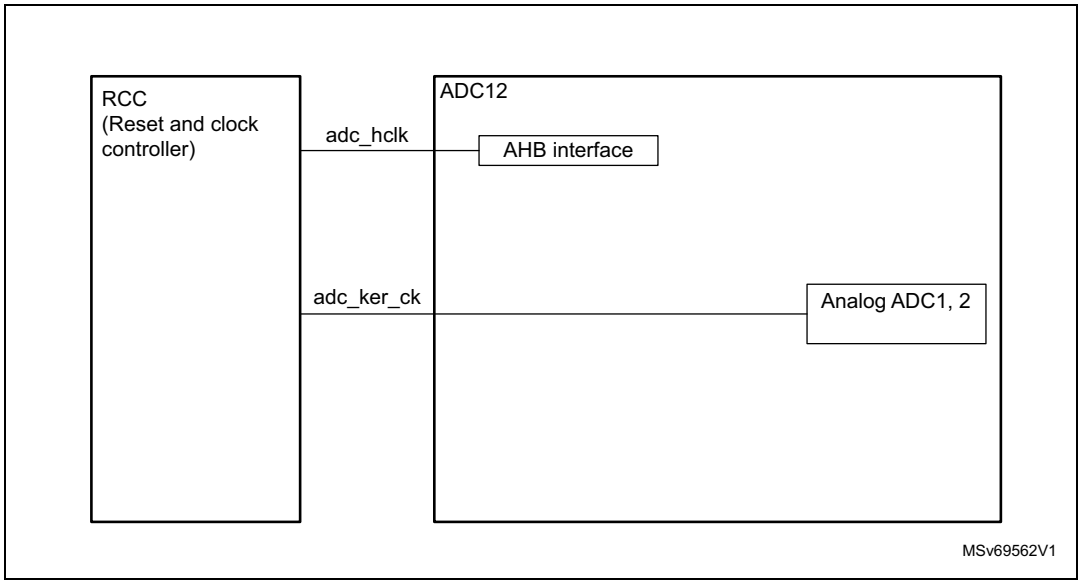
22.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 120: ADC clock scheme*). This selection is done in the RCC (refer to section *Reset and clock control (RCC)* for more information):



1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous from the AHB clock.
2. The ADC clock can be derived from AHB clock (selected in RCC).

Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected.

Option **2** corresponds to a pseudosynchronous clock. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains). This accurate trigger is supported only by trgo or trgo2 timer triggers.

The clock is configured through the RCC and must be compliant with the operating frequency specified in the device datasheet.

Figure 120. ADC clock scheme

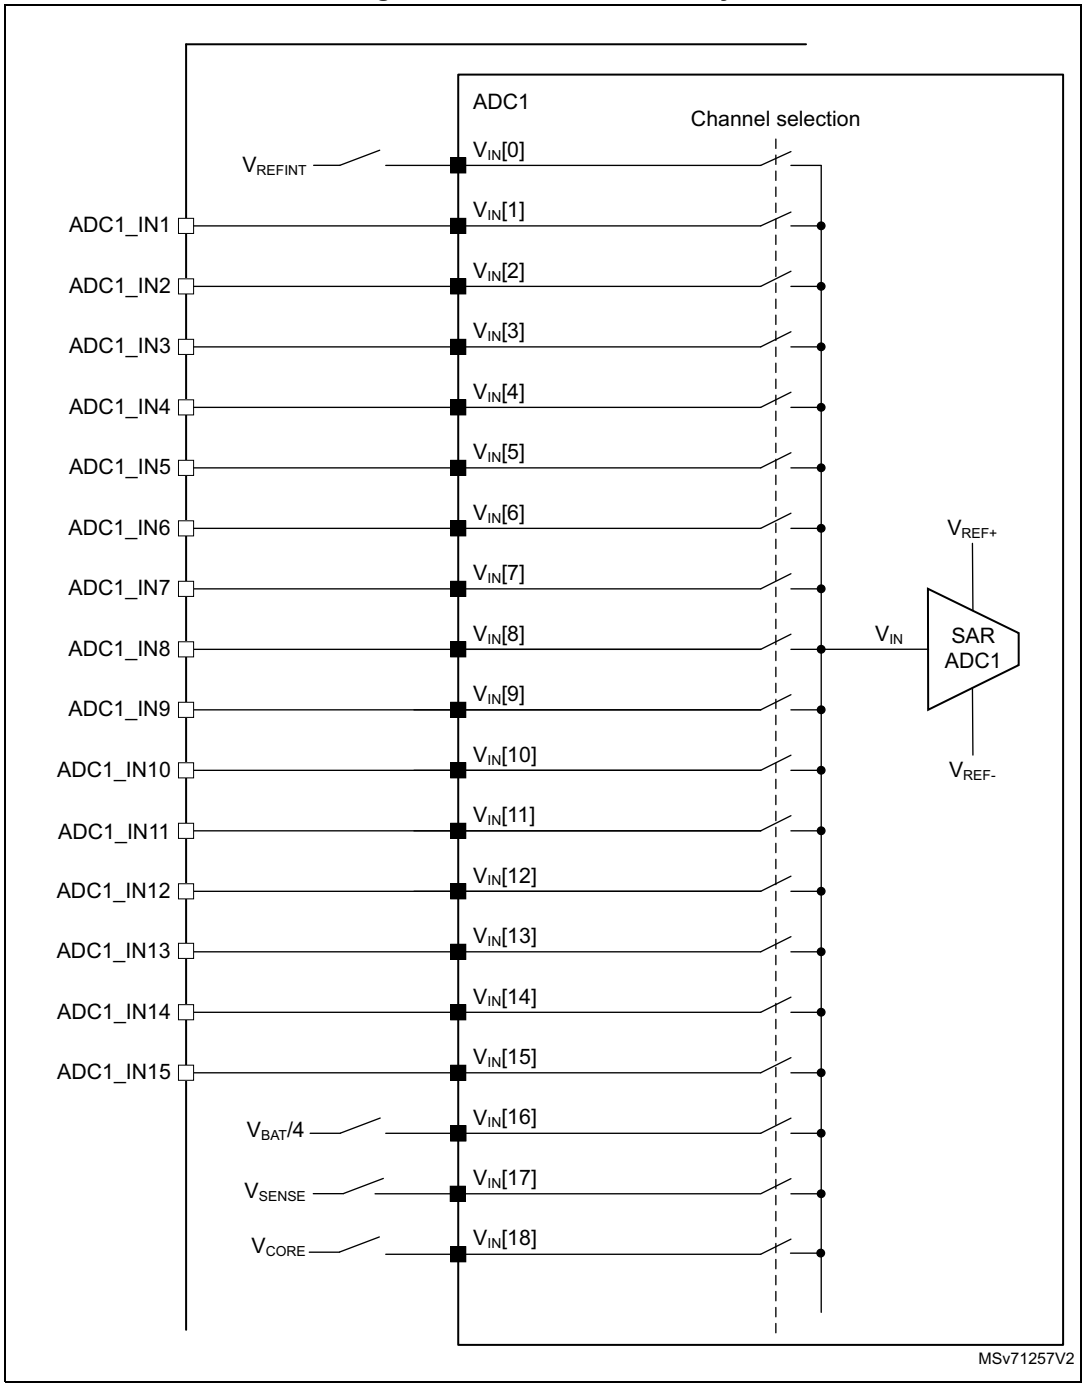
Clock ratio constraint between ADC clock and AHB clock

There are no constraints to respect for the ratio between the ADC clock and the AHB clock. However, the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.

22.4.4 ADC connectivity

ADC inputs are connected to external channels as well as internal sources as described below.

Figure 121. ADC1 connectivity



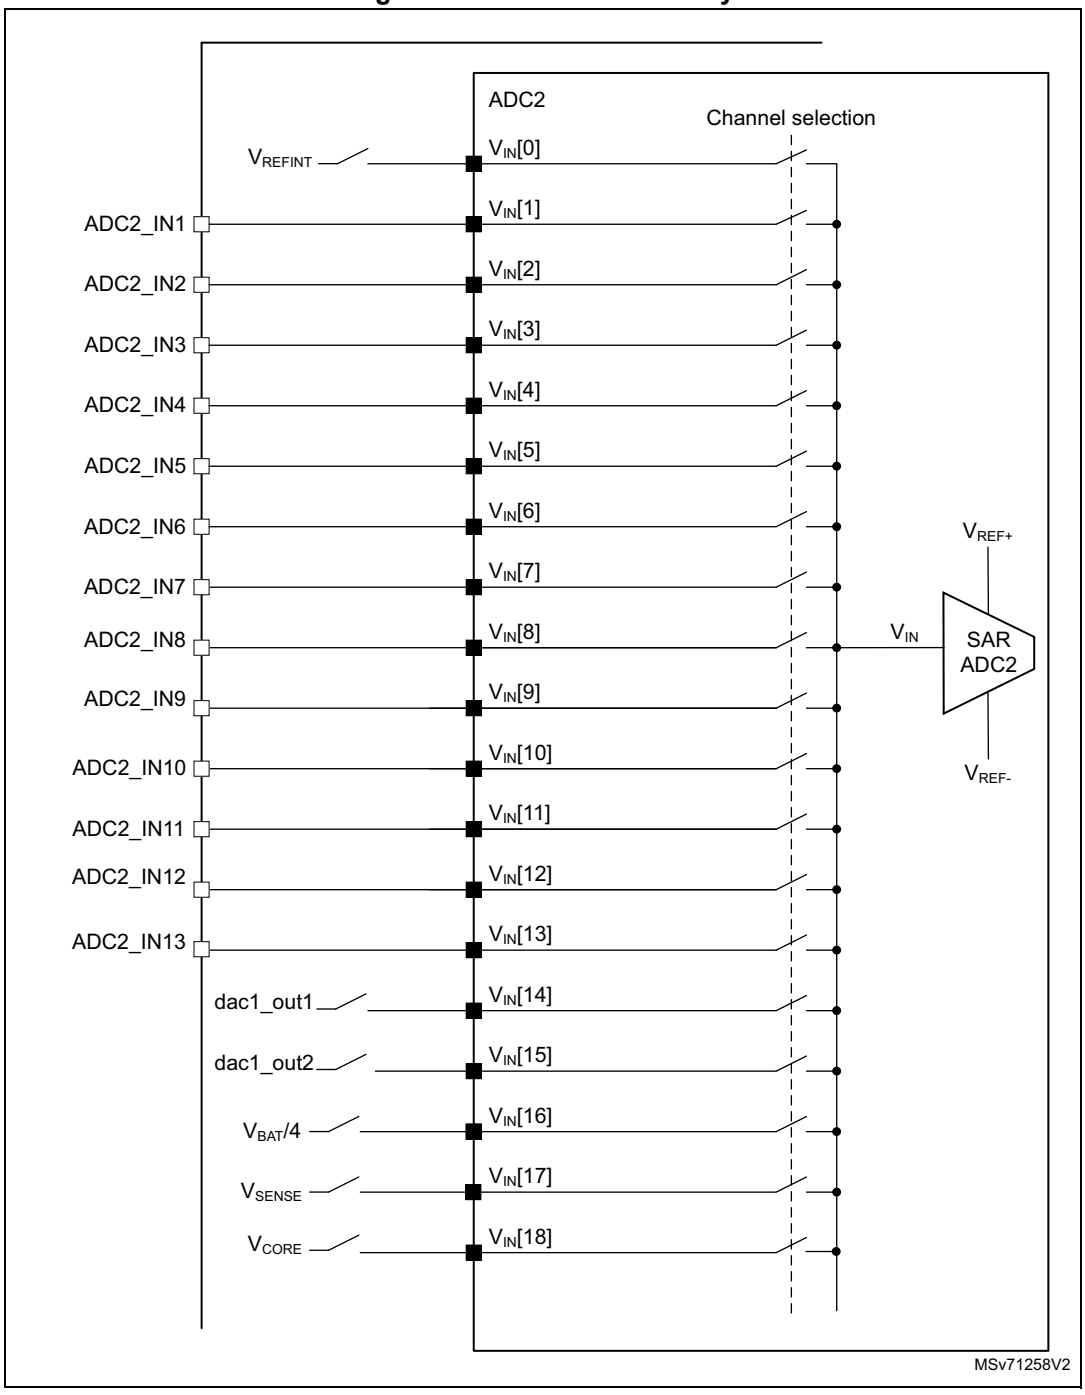


Figure 122. ADC2 connectivity

22.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

22.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of the DEEPPWD bit is 1 in the ADC_CR register).

To start ADC operations, it is first required to exit Deep-power-down mode by clearing the DEEPPWD bit.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the ADVREGEN bit of the ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software. For the startup time of the ADC voltage regulator, refer to the device datasheet for $T_{ADCVREG_STUP}$ parameter.

When ADC operations are complete, the ADC can be disabled by clearing the ADEN bit of ADC_CR. Power can then be saved by disabling the ADC voltage regulator (by clearing ADVREGEN).

Additional power can be saved by entering ADC Deep-power-down mode again (by setting DEEPPWD of ADC_CR register). This is particularly interesting before entering Stop mode.

Note: Setting DEEPPWD automatically disables the ADC voltage regulator and the ADVREGEN bit is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN cleared), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or reapply the calibration factor, which was previously saved (refer to *Section Calibration*).

22.4.7 Calibration (ADCAL)

A software calibration is required before launching the ADC. During the calibration procedure, the ADC calculates a calibration factor, which is applied internally to the ADC until the next ADC power-off. During the calibration, the application must not use the ADC and must wait until the calibration is complete.

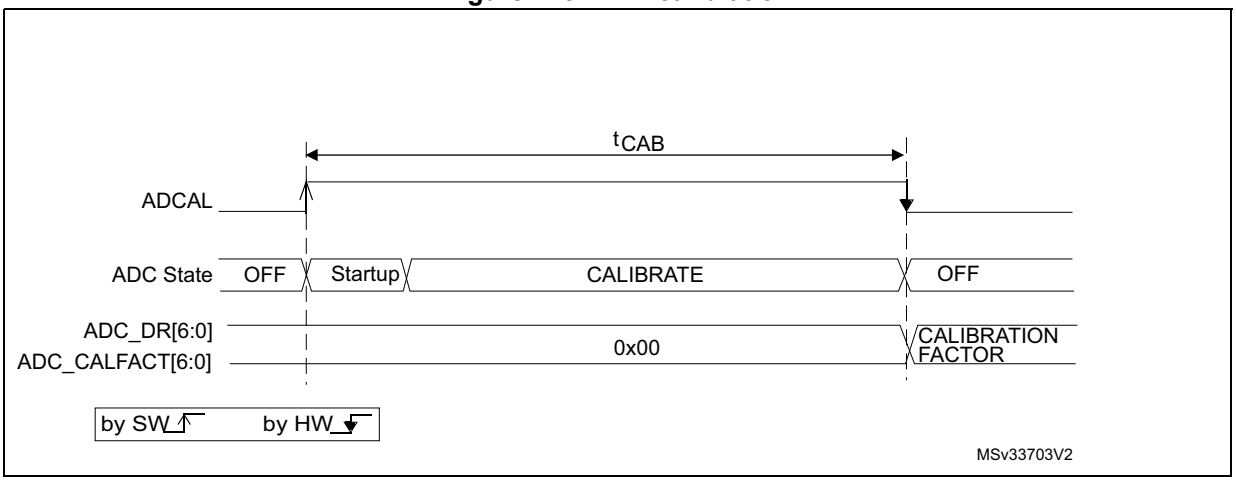
The calibration is preliminary to any ADC operation. It removes the offset error, which may vary from chip to chip due to process, voltage and temperature variation.

The calibration is initiated by software by setting the ADCAL bit. It can be initiated only when all the following conditions are met:

- The ADC voltage regulator is enabled (ADVREGEN = 1 and LDORDY = 1).
- The ADC is disabled (ADEN = 0).

The ADCAL bit stays at 1 during all the calibration sequence. It is then deasserted by hardware as soon the calibration completes. At this time, the calibration factor can be read from the bits 6 to 0 of the ADC_DR register. The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, when the ADC operating conditions change (the main contributor to ADC offset variations is V_{DDA}, and the temperature to a lesser extent), rerun a calibration cycle. It is recommended to recalibrate the ADC when the V_{DDA} voltage changed more than 10%.

The internal analog calibration is lost in the following cases:



- The ADC power is removed (for example, when the product enters standby mode). Still, to avoid spending time recalibrating the ADC, it is possible to save and restore the calibration factor by software (provided the temperature and voltage are stable during the ADC power-down).
- The ADC is reset.

The calibration factor can be written if the ADC is enabled but no conversions are ongoing (ADEN = 1 and ADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion.

Software procedure to calibrate the ADC

1. Ensure ADEN = 0, ADVREGEN = 1, AUTOFF = 0, DEEPPWD = 0, and DMAEN = 0.
2. Set ADCAL.
3. Wait until ADCAL = 0 (or until EOCAL = 1). This can be handled by interrupt if the interrupt is enabled by setting the EOCALIE bit of the ADC_IER register.
4. The calibration factor can be read from bits 6 to 0 of the ADC_DR or ADC_CALFACT register.

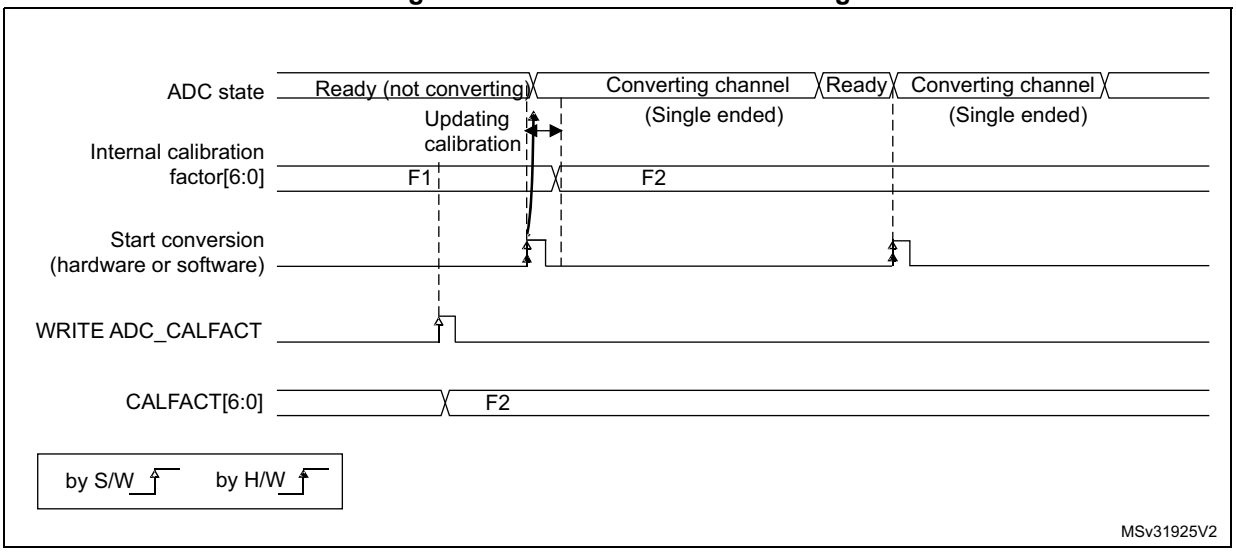


Figure 123. ADC calibration

Software procedure to force the calibration factor

1. Ensure ADEN and ADSTART = 0 (ADC started with no conversion ongoing).
2. Program the saved calibration factor to the ADC_CALFACT register.
3. The calibration factor is used as soon as a new conversion is launched.

Figure 124. Calibration factor forcing

22.4.8 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure described in *Section 22.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

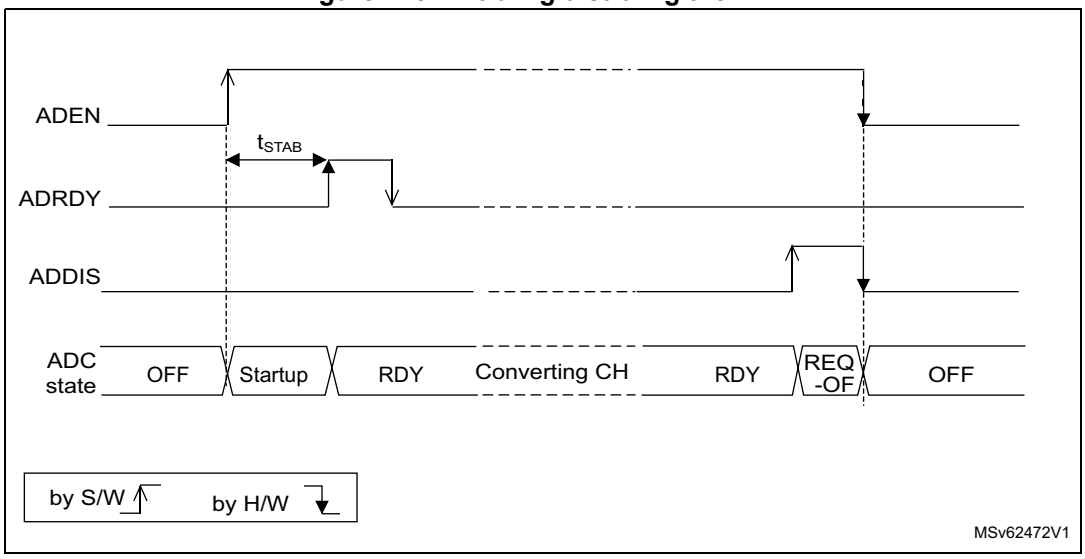
Once DEEPPWD is cleared and ADVREGEN is set, the ADC can be enabled. It requires a t_{STAB} stabilization time before starting converting accurately (see *Figure 125*).

Two control bits enable or disable the ADC:

- Set ADEN to enable the ADC. The ADRDY flag is set once the ADC is ready for operation.
- Set ADDIS to disable the ADC. ADEN and ADDIS are automatically deasserted by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to *Section 22.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*) or when an external trigger event occurs if triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs, if injected triggers are enabled.



Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by programming it to 1.
2. Set ADEN.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE must be set).
4. Clear the ADRDY bit in the ADC_ISR register by programming it to 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop all regular and injected ongoing conversions by setting ADSTP and JADSTP. Then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait for ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 125. Enabling/disabling the ADC

22.4.9 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC section) and configure the ADEN bit in the ADC_CR register, only if the ADC is disabled (ADEN must be cleared).

The software can then write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if no regular conversions are ongoing (ADSTART must be cleared).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if no injected conversions are ongoing (JADSTART must be cleared).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to *Section 22.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)* for details).
- To modify the all above control bits when the software trigger function is used, an ADSTP or JADSTP must be issued to make sure all activities are stopped, even if ADSTART and JADSTART are cleared.

The software is allowed to write the ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and if there is no pending request to disable the ADC. In addition, the software can write the ADC_JSQR register only if JADSTART is cleared and no injected conversion is ongoing. Refer to *Section 22.7.14: ADC injected sequence register (ADC_JSQR)* for additional details.

Note: There is no hardware protection to prevent forbidden write accesses to ADC control bits. In such cases, the ADC state may become unknown. To recover from this situation, the ADC must be disabled (ADEN = 0 as well as all the bits of the ADC_CR register).

22.4.10 Channel selection (ADC_SQRy, ADC_JSQR)

The ADC features up to 19 multiplexed channels per ADC, out of which:

- Up to 15 analog inputs coming from GPIO pads (ADCx_IN[i]). Depending on the device, not all of them are available on GPIO pads.
- The ADC is connected to up to 6 internal analog inputs:
  - internal reference voltage (V_{REFINT})
  - Internal temperature sensor (V_{SENSE})
  - V_{BAT} monitoring channel ($V_{BAT}/4$)
  - V_{CORE} voltage
  - DAC internal channel

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VREFEN, TSEN, VBATEN in the ADCC_CCR registers, or by enabling the corresponding bit in the *ADC option register (ADC_OR)*.

Refer to *ADC interconnection* tables in *Section 22.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to ADC pins.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_IN3, ADCx_IN8, ADCx_IN2, ADCx_IN2, ADCx_IN0, ADCx_IN2, and ADCx_IN2.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The

total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An **injected group** is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while a regular conversion is ongoing. ADC regular conversions must consequently be stopped by setting ADSTP (refer to *Section 22.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)*).

In addition, the ADC_JSQR register must not be modified while an injected conversion is ongoing. ADC injected conversions must consequently be stopped by setting JADSTP, except when JQDIS is cleared.

22.4.11 Channel preselection register (ADC_PCSEL)

The PCSEL bit of the ADC_PCSEL register controls the analog switch integrated in the I/O.

For each channel selected through SQRx or JSQRx bits, the corresponding PCSEL bit must be configured in advance in the ADC_PCSEL register. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed. The analog switch integrated in the I/O cannot react as fast as the ADC multiplexer. To avoid the delay due to the analog switch control on the I/O, it is necessary to preselect the input channels that are selected through the SQRx and JSQRx. The selection is based on the V_{IN} of each ADC input. For example, if the ADC converts ADCx_IN1, PCSEL1 bit must also be set in ADC_PCSEL register.

Note: Configuring the PCSEL bit is not necessary for the internal channels (such as V_{REFINT}).

22.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be sufficient for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time, which is programmable through the SMP[2:0] bits of the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 6.5 ADC clock cycles
- SMP = 011: 11.5 ADC clock cycles
- SMP = 100: 23.5 ADC clock cycles
- SMP = 101: 46.5 ADC clock cycles
- SMP = 110: 246.5 ADC clock cycles
- SMP = 111: 1499.5 ADC clock cycles

The total conversion time is calculated as follows:

$$T_{CONV} = \text{Sampling time} + 12.5 \text{ ADC clock cycles}$$

Example

With $F_{adc_ker_ck}$ = 30 MHz and a sampling time of 2.5 ADC clock cycles:

$$T_{CONV} = (2.5 + 12.5) \times \text{ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns}$$

The ADC notifies the end of the sampling phase by asserting the EOSMP flag (only for regular conversion).

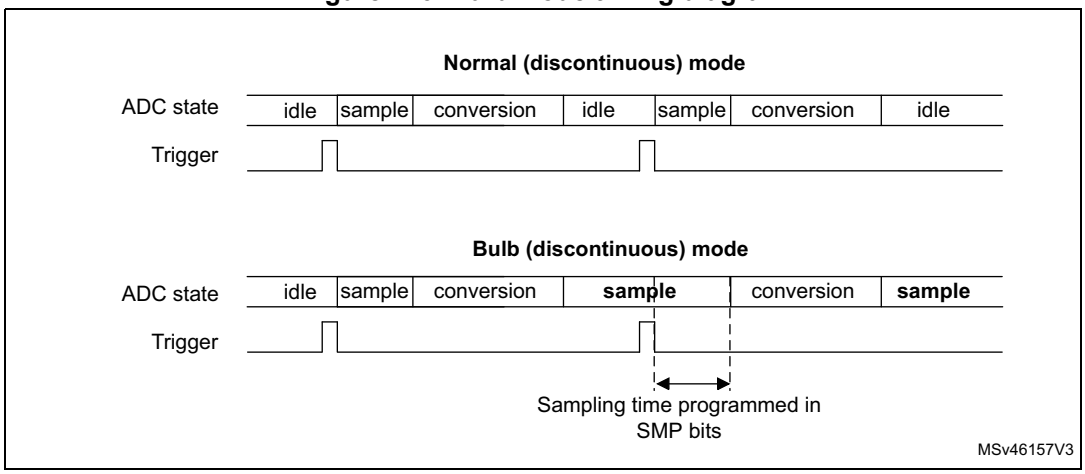
Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum and a maximum sampling times as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

The bulb sampling mode enables to obtain longer sampling time.

When the BULB bit is set in the ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.



The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

The BULB bit can be modified only when the ADEN bit of the ADC_CR register is cleared.

When the BULB bit is set, it is not allowed to set the SMPTRIG bit in ADC_CFGR2.

Figure 126. Bulb mode timing diagram

Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed through SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected (EXTEN[1:0] = 01), each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

Due to the synchronization mechanism, the minimum allowed pulse width is seven adc_ker_ck periods.

When a software trigger is selected (EXTEN[1:0] = 00), the software trigger is not the ADSTART bit of ADC_CR but the SWTRIG bit. The SWTRIG bit has to be set to start the sampling period, and it has to be cleared to end the sampling period and start the conversion. In this mode, the minimum sampling time is limited to seven ADC clock cycles.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is only compatible with the discontinuous mode. DISCNUM must be cleared for regular conversion mode. It is not supported for injected conversion mode and autoinjection mode.

When the SMPTRIG bit is set, setting the BULB bit is not allowed and injected conversions are not supported.

The sampling time control trigger mode is not compatible with the following dual modes: DUAL[4:0] = 0b00010, 0b00011, 0b00101, 0b00110, 0b00111, and 0b01001.

22.4.13 Single conversion mode

To enable the single conversion mode for regular channels, clear both CONT and DISCEN bits in ADC_CFGR1 register. To enable it on injected channel, clear JDISCEN bit.

In single conversion mode, the ADC performs once all the regular conversions of the programmed channels. This mode is started by one of the following events:

- ADSTART bit set in the ADC_CR register (for a regular channel)
- JADSTART bit set in the ADC_CR register (for an injected channel)
- An external hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit 8-level FIFO accessible through the ADC_DR register,
- The EOC (end of regular conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers,
- The JEOC (end of injected conversion) flag is set, and
- An interrupt is generated if the JEOCIE bit is set.

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set, and
- An interrupt is generated if the JEOSIE bit is set.

The ADC then stops until a new external regular or injected trigger occurs or until the ADSTART or JADSTART bit is set again.

The single conversion mode is compatible with bulb and sampling time control trigger modes.

Note: To convert a single channel, program a sequence with a length of 1.

22.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts all the conversions of the sequence. This mode is started by setting the CONT bit of the ADC_CFGR1 register, either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the eight 32-bit word FIFO accessible through the ADC_DR register.
- The EOC (end of conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled, this means that it is forbidden to set both DISCEN and CONT bits.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit) (refer to Section : Autoinjection mode).

22.4.15 Starting conversions (ADSTART, JADSTART)

ADC regular conversions can be started by setting ADSTART.

When ADSTART is set, the conversion starts:

- Immediately if EXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 00.

The application software starts ADC injected conversions by setting JADSTART.

When JADSTART is set, the conversion starts:

- Immediately if JEXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected injected hardware trigger, if JEXTEN[1:0] is not equal to 00.

Note: In autoinjection mode (JAUTO = 1), use the ADSTART bit to start regular conversions followed by autoinjected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether an ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both cleared, indicating that the ADC is idle.

ADSTART is deasserted by hardware:

- In single mode with software regular trigger (CONT = 0, EXTEN = 0x0): at any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT and EXTEN don't care), after execution of the ADSTP procedure asserted by the software

Note: In continuous mode (CONT = 1), ADSTART is not deasserted by hardware when EOS is asserted because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN ≠ 0x00), ADSTART is not deasserted by hardware when EOS is asserted to help the software that does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

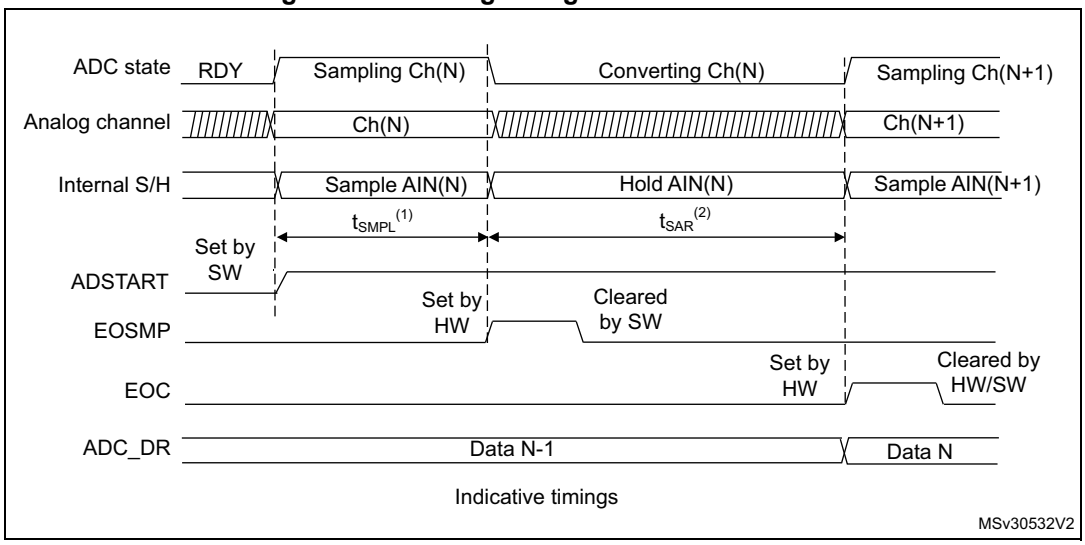
JADSTART is deasserted by hardware:

- In single mode with software injected trigger (JEXTEN = 0x0): at the end of each injected conversion sequence (JEOS assertion) or at the end of each subgroup processing if JDISCEN = 1
- In all cases (JEXTEN=x), after execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

In bulb mode (BULB = 1), the previous end-of-conversion automatically starts the sampling, then setting ADSTART starts the conversion including the programmed sampling time.

In sampling time control trigger mode (SMPTRIG = 1), SWTRIG bit must be set to start the conversion.



22.4.16 Timing

The elapsed time between the start of a conversion and the end of a conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [2.5\ _{|min} + 12.5\ _{|12bit}] \times T_{ADC_CLK}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 83.333\ ns\ _{|min} + 416.667\ ns\ _{|12bit} = 500\ ns$ (for $F_{adc_ker_ck} = 30$ MHz)

Figure 127. Analog-to-digital conversion time

1. t_{SMPL} depends on SMP[2:0].
2. t_{SAR} depends on RES[2:0].
3. The bulb and the sampling time control trigger modes are not described in the above figure.

22.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop ongoing regular conversions by setting ADSTP and ongoing injected conversions by setting JADSTP.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice versa. This allows, for instance, the reconfiguration of the injected conversion sequence and triggers while regular conversions are still ongoing (and vice versa).

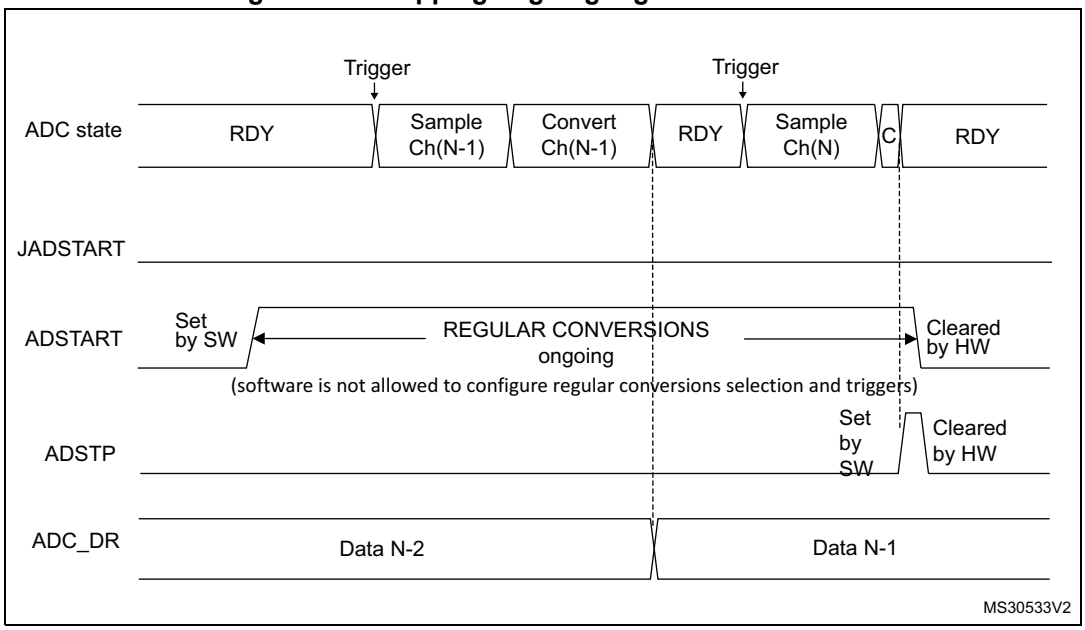
When the ADSTP bit is set by software, any ongoing regular conversion is aborted with the partial result discarded (the ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (the ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC restarts a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (for regular conversion), or JADSTP/JADSTART bits (for injected conversion) are deasserted by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In autoinjection mode (JAUTO = 1), setting the ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 128. Stopping ongoing regular conversions



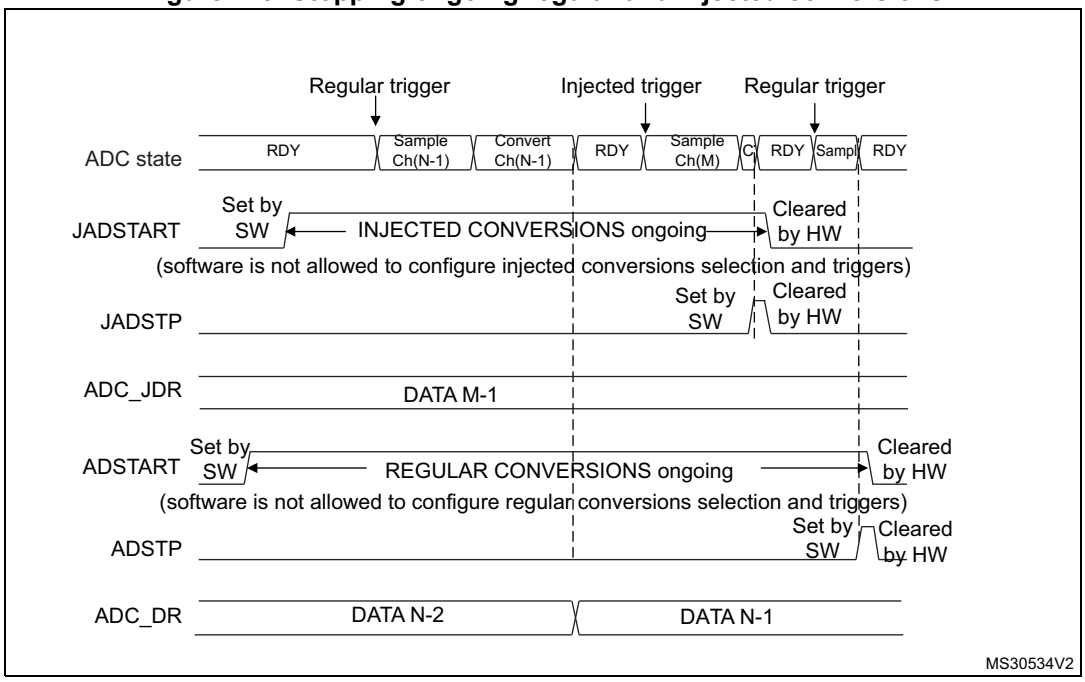


Figure 129. Stopping ongoing regular and injected conversions

22.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (for example timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once the software has set ADSTART while the injected trigger selection is effective once the software has set JADSTART bit.

All hardware triggers that occur while a conversion is ongoing are ignored:

- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 179 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 179. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware trigger detection disabled, software trigger detection enabled
01	Hardware trigger with detection on the rising edge (sampling time controlled in hardware trigger mode)
10	Hardware trigger with detection on the falling edge
11	Hardware trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

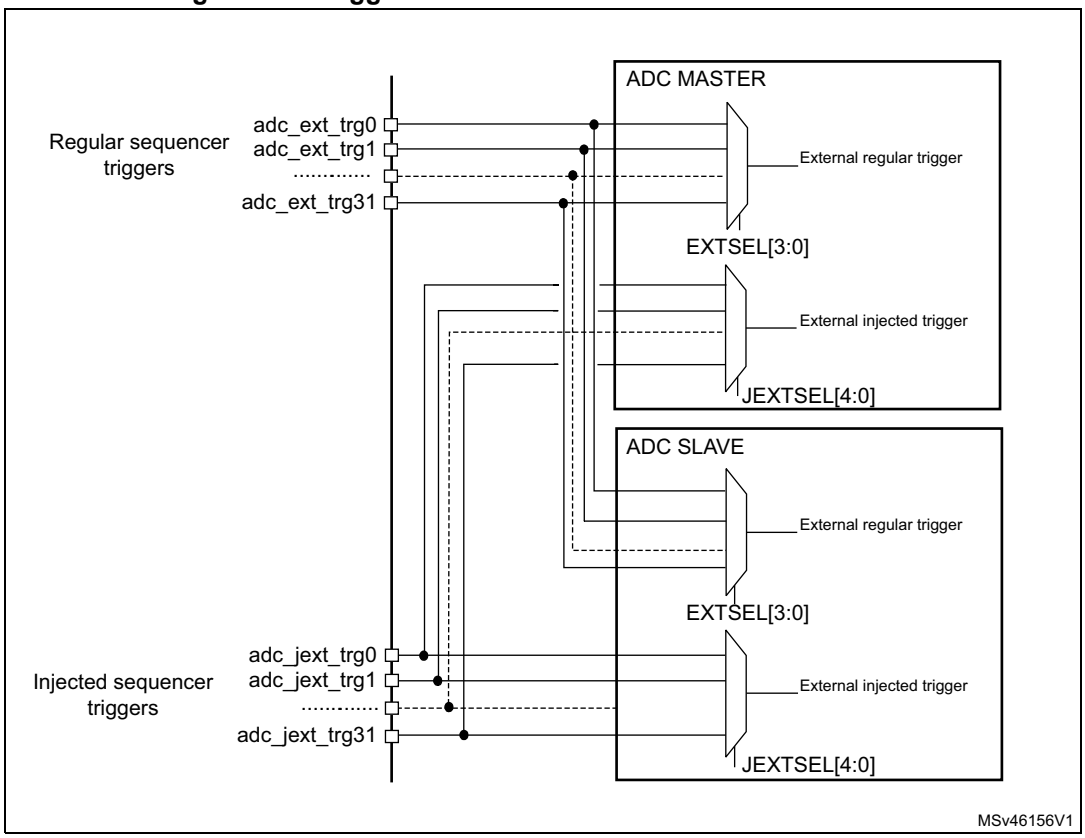

Table 180. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

The EXTSEL and JEXTSEL control bits select which, out of 32 possible events, can trigger the conversion of the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Figure 130. Triggers shared between ADC master and slave

Refer to *ADC interconnection* tables in *Section 22.4.2: ADC pins and internal signals* for the list of the external triggers that can be used for regular conversion.

22.4.19 Injected channel management

Triggered injection mode

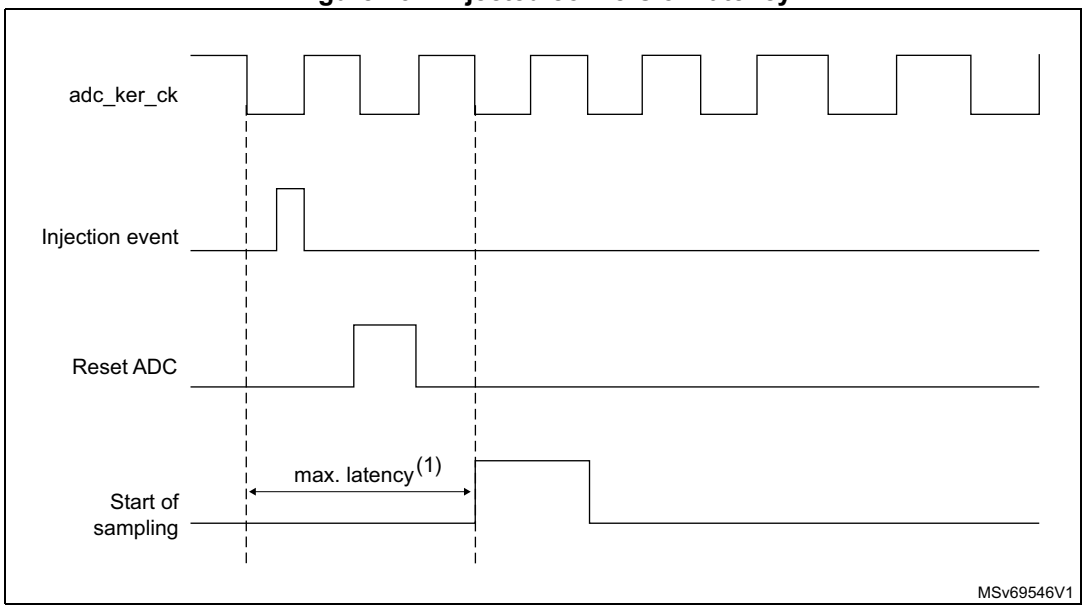
To use triggered injection, the JAUTO bit in the ADC_CFGR1 register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once if JDISCEN = 0).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 131* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 28 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 29 ADC clock cycles.

Autoinjection mode

If the JAUTO bit in the ADC_CFGR1 register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.



In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the autoinjected and discontinuous modes simultaneously.

Figure 131. Injected conversion latency

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

22.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11

  - First trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - Second trigger: channels converted are 6, 7, 8 (an EOC event is generated at the end of each conversion).
  - Third trigger: channels converted are 9, 10, 11 (an EOC event is generated at the end of each conversion) and an EOS event is generated after the conversion of channel 11.
  - Fourth trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all devices.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the fourth trigger reconverts the channels 1, 2 and 3 in the first subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - First trigger: channel 1 converted (a JEOC event is generated)
  - Second trigger: channel 2 converted (a JEOC event is generated)
  - Third trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all devices.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the fourth trigger reconverts the first injected channel 1.

It is not possible to use both autoinjection mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

22.4.21 Queue of context for injected conversions

A queue of context is implemented to anticipate up to two contexts for the next injected sequence of conversions. JQDIS bit of the ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:

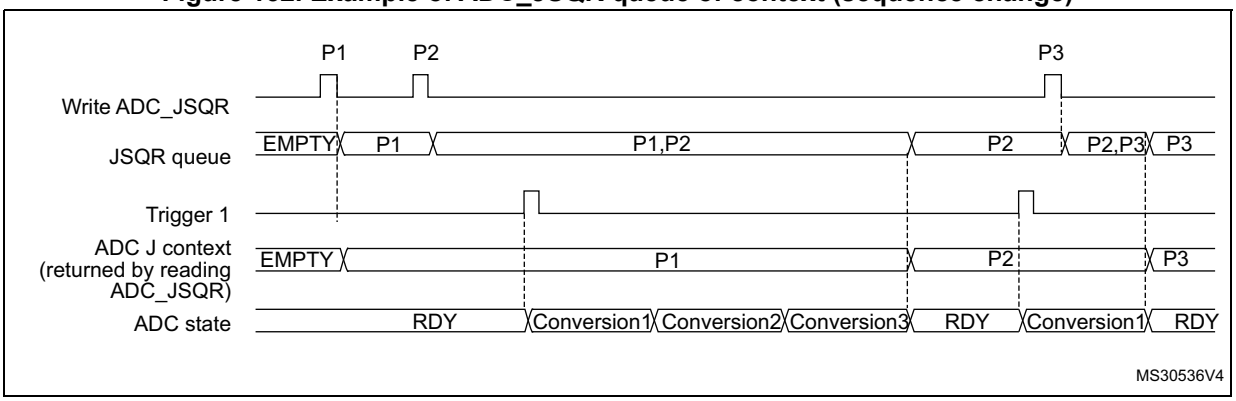
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in the ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in the ADC_JSQR register)

All the parameters of the context are defined in a single register ADC_JSQR and this register implements a queue of two buffers, allowing the bufferization of up to two sets of parameters:

- The ADC_JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written to the ADC_JSQR register is stored into the queue of context.
- At the beginning, the queue is empty and the first write access to the ADC_JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the queue is consumed and the context changes according to the next ADC_JSQR parameters stored in the queue. This new context is applied for the next injected sequence of conversions.
- A queue overflow occurs when writing to the ADC_JSQR register while the queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of ADC_JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the queue becomes empty, depending on the value of the JQM control bit of the ADC_CFGR register:
  - If JQM = 0, the queue is empty just after enabling the ADC, but then it can never be empty during run operations: the queue always maintains the last active

context and any further valid start of the injected sequence is served according to the last active context.

  - If JQM = 1, the queue can be empty after the end of an injected sequence or if the queue is flushed. When this occurs, there is no more context in the queue and hardware writes a new injected context into the ADC_JSQR register.
- Reading the ADC_JSQR register returns the current the ADC_JSQR context which is active at that moment. When the ADC_JSQR context is empty, the JSQi is read as 0x00.
- The queue is flushed when stopping injected conversions by setting JADSTP or when disabling the ADC by setting ADDIS:
  - If JQM = 0, the queue is maintained with the last active context.
  - If JQM = 1, the queue becomes empty and triggers are ignored.



Note: When configured in discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the queue. The first trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- *First trigger, discontinuous. Sequence 1: context 1 consumed, first conversion carried out*
- *Second trigger, disc. Sequence 1: Second conversion.*
- *Third trigger, discontinuous. Sequence 1: Third conversion.*
- *Fourth trigger, discontinuous. Sequence 2: context 2 consumed, first conversion carried out.*
- *Fifth trigger, discontinuous. Sequence 2: Second conversion.*
- *Sixth trigger, discontinuous. Sequence 2: Third conversion.*

Behavior when changing the trigger or sequence context

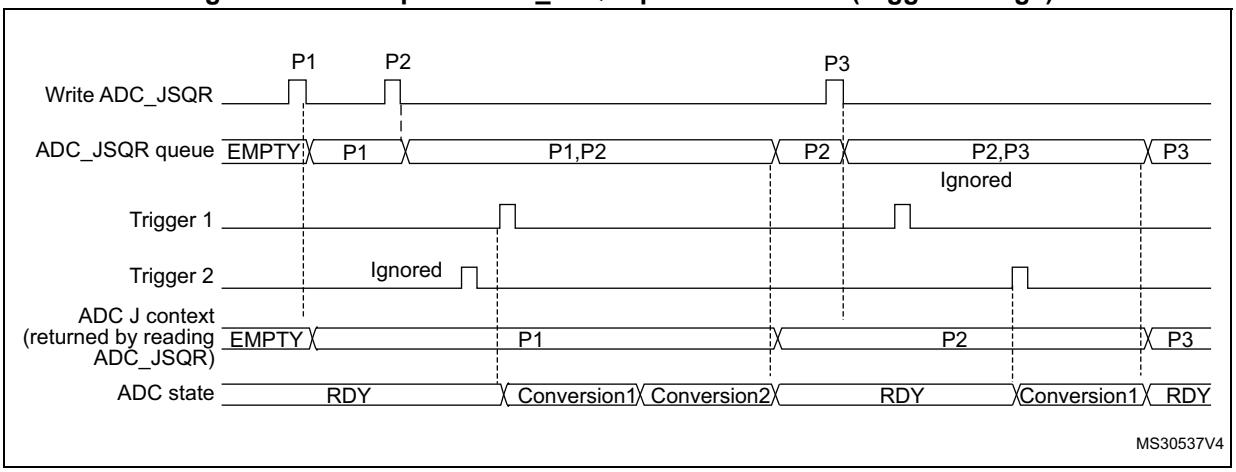


Figure 132 and *Figure 133* show the behavior of the context queue when changing the sequence or the triggers.

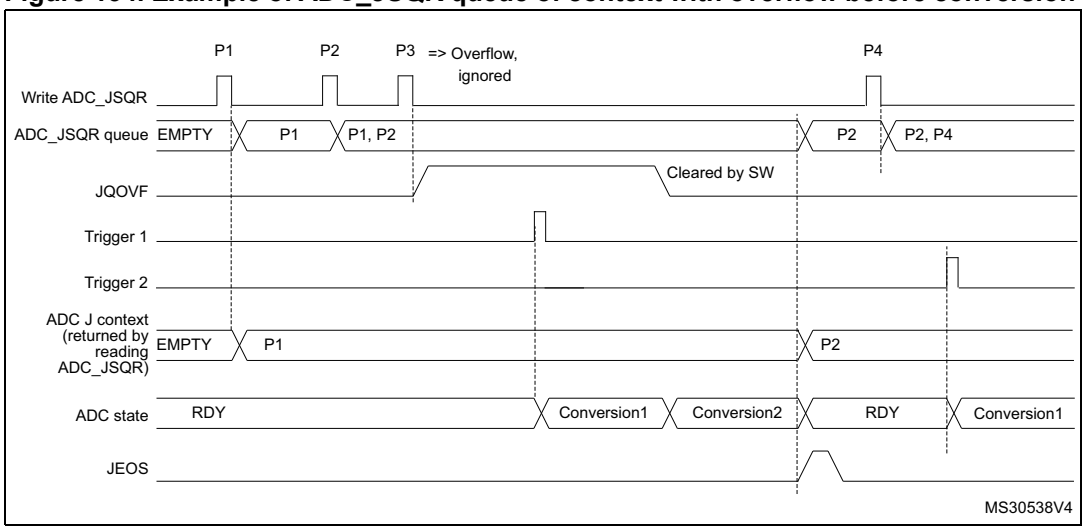
Figure 132. Example of ADC_JSQR queue of context (sequence change)

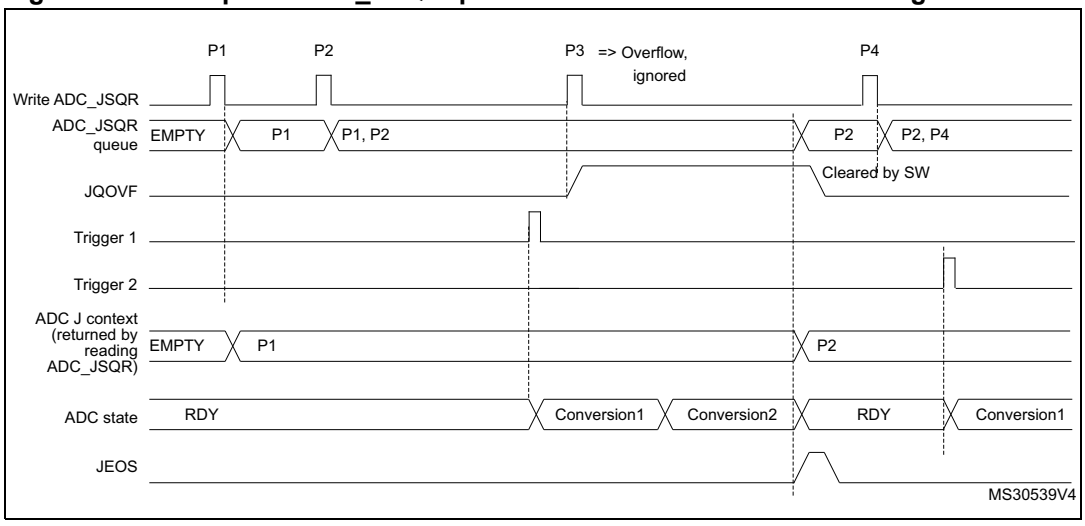
1. Parameters:
   P1: sequence of 3 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 4 conversions, hardware trigger 1

Figure 133. Example of ADC_JSQR queue of context (trigger change)



1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 4 conversions, hardware trigger 1

Queue of context: Behavior when a queue overflow occurs



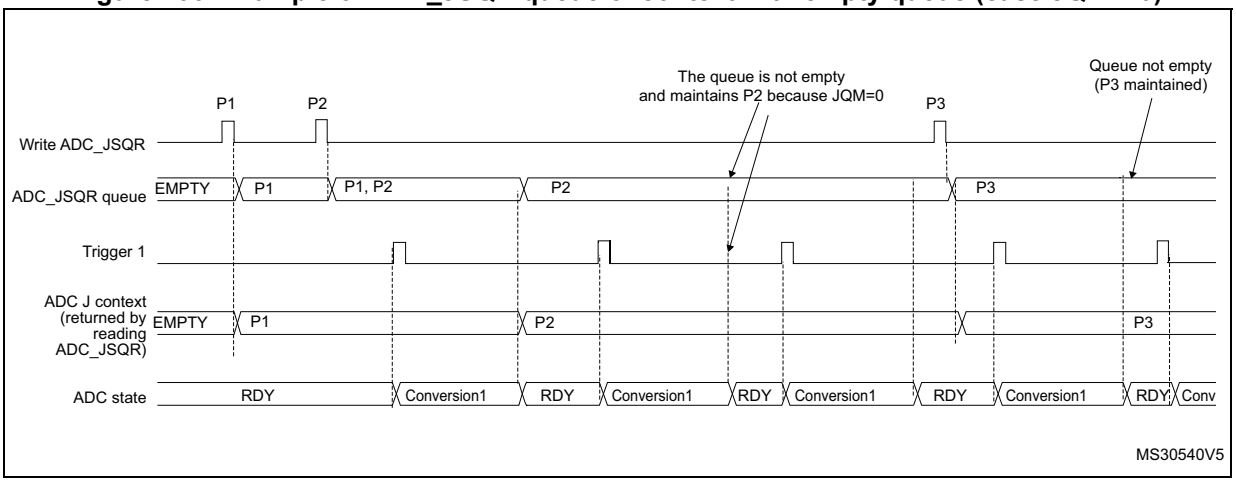
The *Figure 134* and *Figure 135* show the behavior of the context queue if an overflow occurs before or during a conversion.

Figure 134. Example of ADC_JSQR queue of context with overflow before conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1

Figure 135. Example of ADC_JSQR queue of context with overflow during conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1



It is recommended to manage the queue overflows as described below:

- After each P context write to the ADC_JSQR register, the JQOVF flag shows if the write has been ignored or not (an interrupt can be generated).
- Avoid queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

Figure 136 and *Figure 137* show the behavior of the context queue when the queue becomes empty in both cases JQM = 0 or 1.

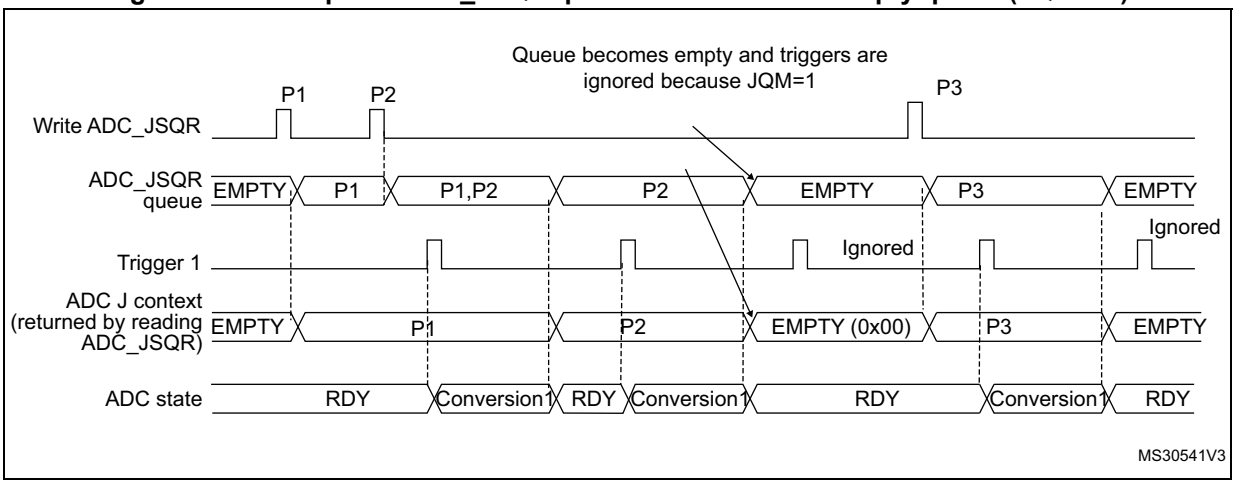


Figure 136. Example of ADC_JSQR queue of context with empty queue (case JQM = 0)

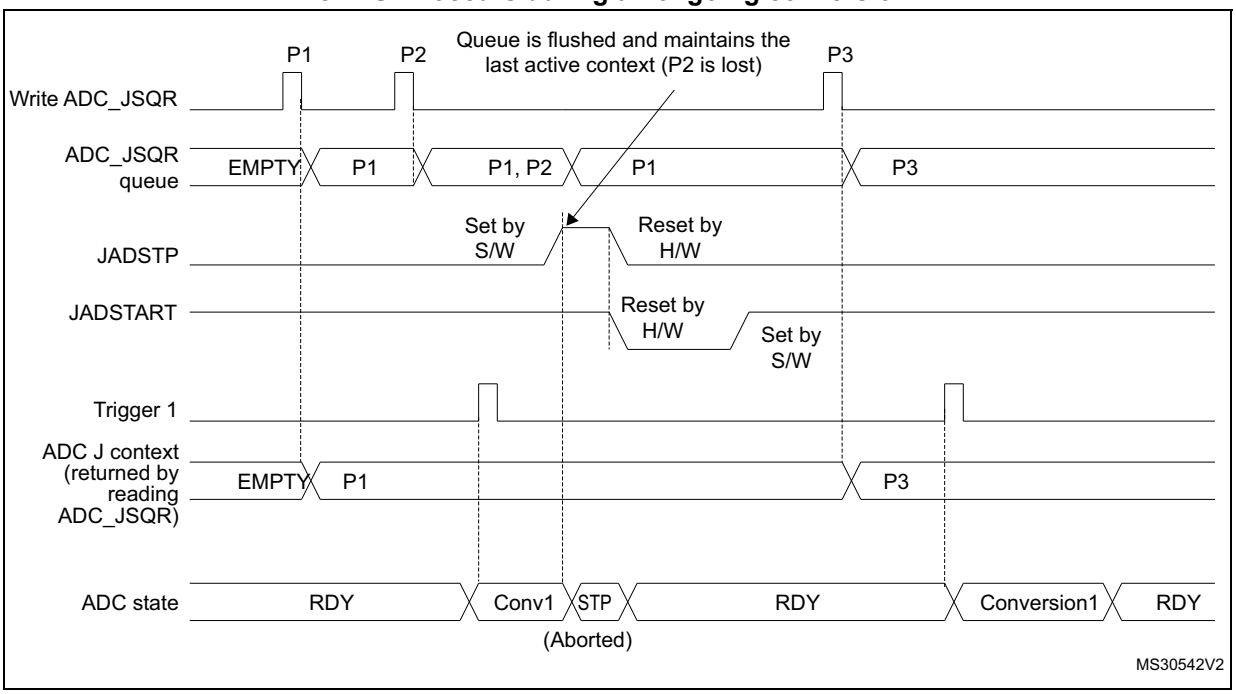
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

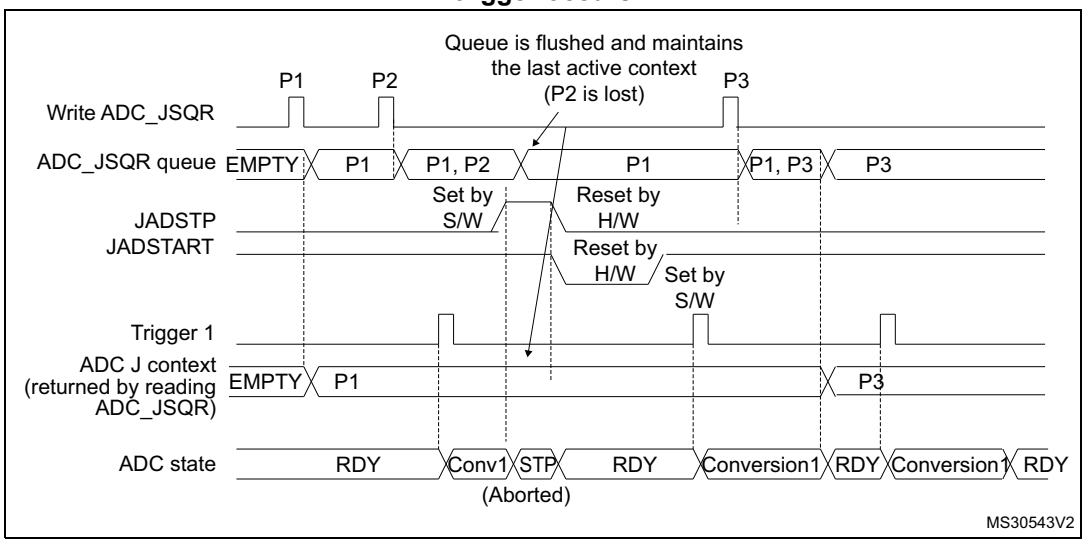
Note: When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.

Figure 137. Example of ADC_JSQR queue of context with empty queue (JQM = 1)



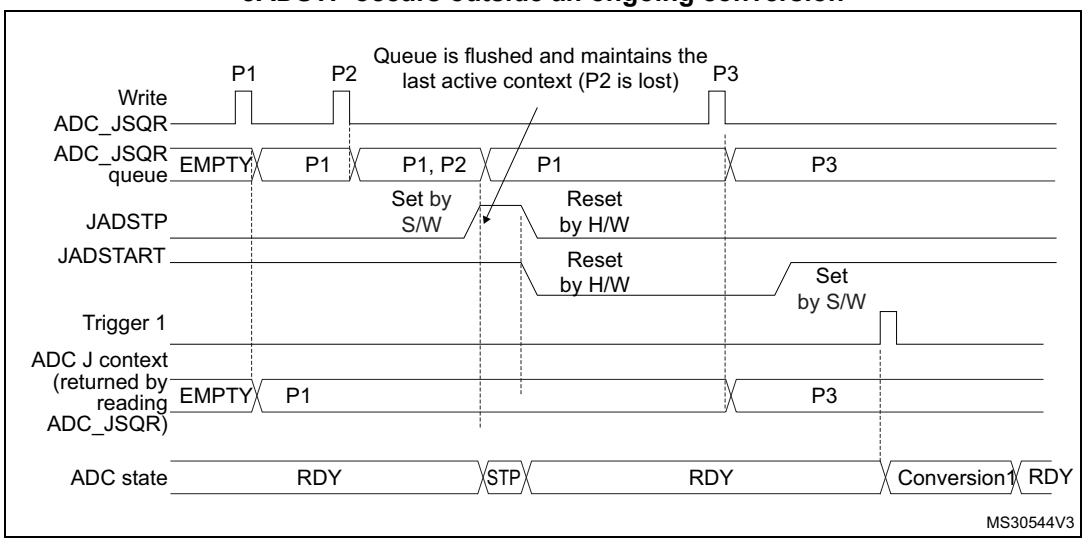
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Flushing the queue of context



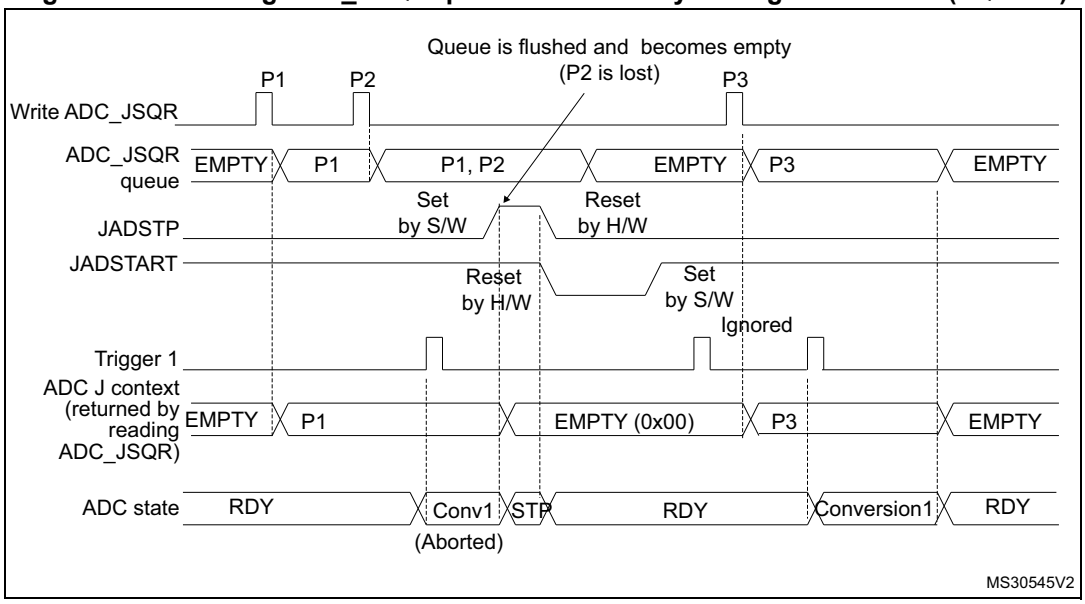
The figures below show the behavior of the context queue in various situations when the queue is flushed.

Figure 138. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.



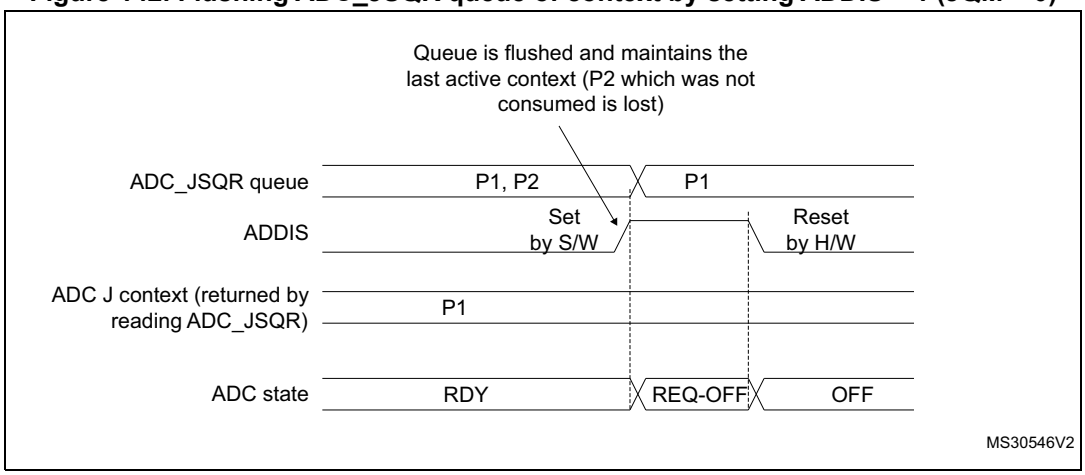
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 139. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs



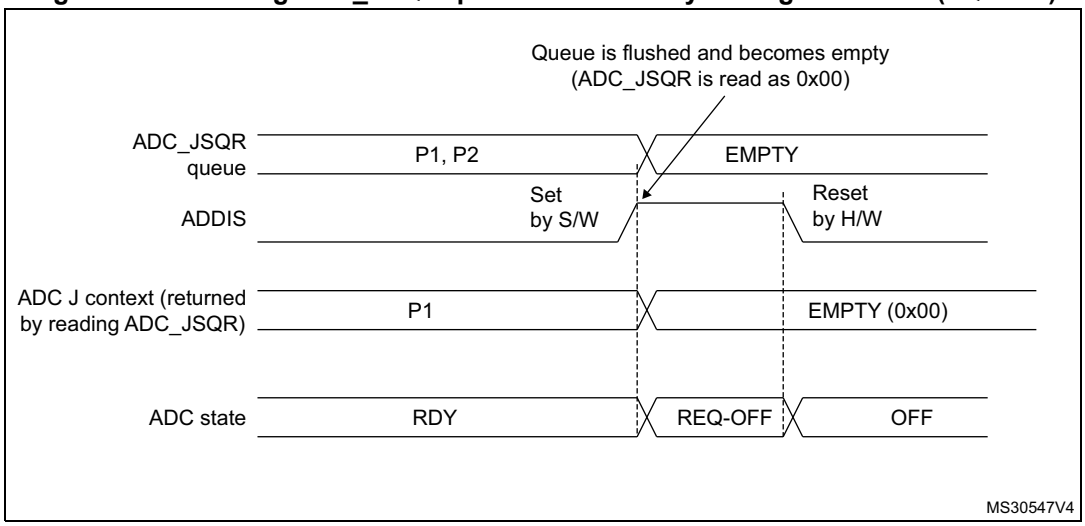
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 140. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 141. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 1)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 142. Flushing ADC_JSQR queue of context by setting ADDIS = 1 (JQM = 0)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 143. Flushing ADC_JSQR queue of context by setting ADDIS = 1 (JQM = 1)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start an ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when the JQM bit is reset:

1. Write a dummy ADC_JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
2. Set JADSTART
3. Set JADSTP
4. Wait until JADSTART is reset
5. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS of the ADC_CFGR register.

22.4.22 Programmable resolution (RES) - fast conversion mode

Faster conversions can be performed by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] control bits. *Figure 148*, *Figure 149*, *Figure 150* and *Figure 151* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to .

Table 181. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$ = 30 MHz	T_{CONV} (ADC clock cycles) (with Sampling time= 2.5 ADC clock cycles)	T_{CONV} (ns) at $F_{adc_ker_ck}$ = 30 MHz
12	12.5 ADC clock cycles	416.667 ns	15 ADC clock cycles	500.0 ns
10	10.5 ADC clock cycles	350 ns	13 ADC clock cycles	433.33 ns
8	8.5 ADC clock cycles	283.33 ns	11 ADC clock cycles	366.67 ns
6	6.5 ADC clock cycles	216.67 ns	9 ADC clock cycles	300 ns

22.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

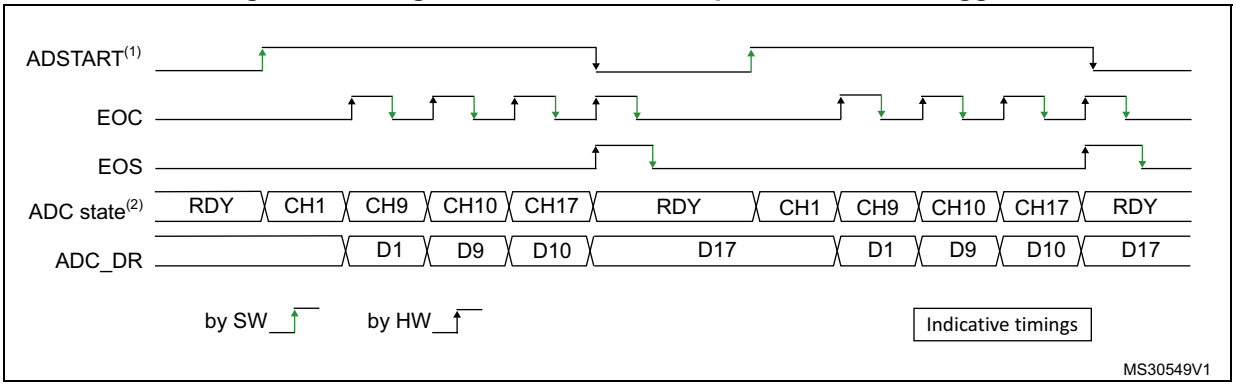
The ADC notifies the application at the end of each regular conversion (EOC) event and injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set. The software can clear the EOC flag either by programming it to 1 or by reading ADC_DR. If ADC_DR FIFO is not emptied, the EOC flag is set again and an interrupt can be generated again.

The ADC sets the JEOC flag as soon as new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if the JEOCIE bit is set. The software can clear the JEOC flag either by programming it to 1 or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of the sampling phase by setting the EOSMP flag (for regular conversions only). The EOSMP flag is cleared by software by programming it to 1. An interrupt can be generated if the EOSMPIE bit is set.

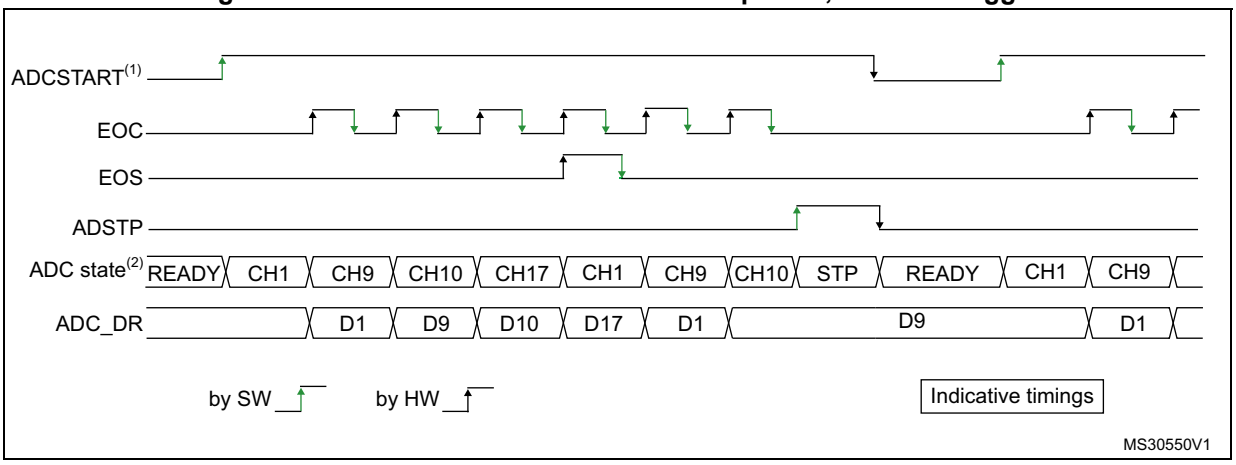
22.4.24 End of conversion sequence (EOS, JEOS)



The ADC notifies the application at the end of each regular sequence (EOS) and injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the conversion of the last data of the regular sequence is complete. An interrupt can be generated if the EOSIE bit is set. The EOS flag is cleared by the software by programming it to 1.

The ADC sets the JEOS flag as soon as the conversion of the last data of the injected sequence is complete. An interrupt can be generated if the JEOSIE bit is set. The JEOS flag is cleared by the software by programming it to 1.



22.4.25 Timing diagram examples (single/continuous modes, hardware/software triggers)

22.4.26 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)

Data and alignment

At the end of each regular channel conversion (when an EOC event occurs), the result of the converted data is stored in the 32-bit wide ADC_DR data register with FIFO. Since the data register has eight levels of FIFO, the EOC flag is raised again as far as the FIFO is not emptied.

At the end of each injected channel conversion (when a JEOC event occurs), the result of the converted data is stored in the 32-bit wide corresponding ADC_JDRy data register.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register select the alignment of the data stored after the conversion. By default, data are right-aligned. Refer to *Figure 148*, *Figure 149*, *Figure 150* and *Figure 151* for examples of data alignment.

Note: The data can be aligned in normal and oversampling mode. The OVSS[3:0] bitfield is only effective in oversampling mode.

Offset

An unsigned offset value y (y = 1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in the OFFSET[21:0] bitfield of the ADC_OFRy register. The channel to which the offset is applied is programmed to the OFFSETy_CH[4:0] bits of ADC_OFCFGRy register. The offset can be positive or negative depending on the value of POSOFF bit. When POSOFF is cleared, the converted value is subtracted by the user-defined offset written in OFFSET[21:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (for example the maximum offset value is 0xFFF in 12-bit mode).

The offset can be used to convert unsigned data to signed data (for example the offset value is equal to 0x800 in 12-bit mode).

The offset correction is also supported in oversampling mode. In this mode, the offset is subtracted when all the oversampling operations are complete.

Note: It is not allowed to select the same channel for different OFFSETy_CH[4:0] values except when OFFSET[21:0] is 0.

Table 186 describes how the computation is performed for all the possible ADC resolutions and offset settings.

Table 182. Offset computation versus data resolution

Resolution (RES[1:0] bits)	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed or unsigned 24-bit data, right aligned to [11:0]	-
01: 10-bit	DATA[11:2],00	OFFSET[11:2]	Signed or unsigned 24-bit data, right aligned to [9:0]	The user must configure OFFSET[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	OFFSET[11:4]	Signed or unsigned 24 bit data right aligned to [7:0]	The user must configure OFFSET[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	OFFSET[11:6]	Signed or unsigned 24 bit data right aligned to [5:0]	The user must configure OFFSET[5:0] to 0b000000.

Figure 148, *Figure 149*, *Figure 150* and *Figure 151* show alignments for signed and unsigned data.

Figure 148. Right alignment (offset disabled, unsigned value)

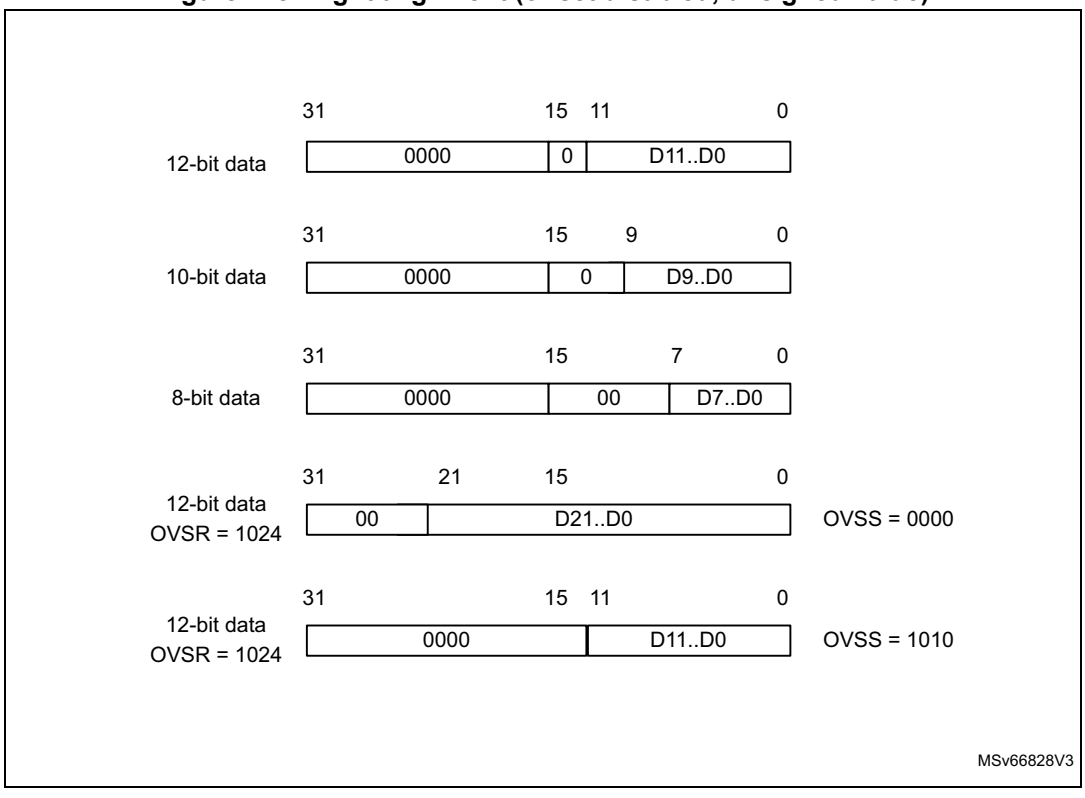

Figure 149. Right alignment (offset enabled, signed value)

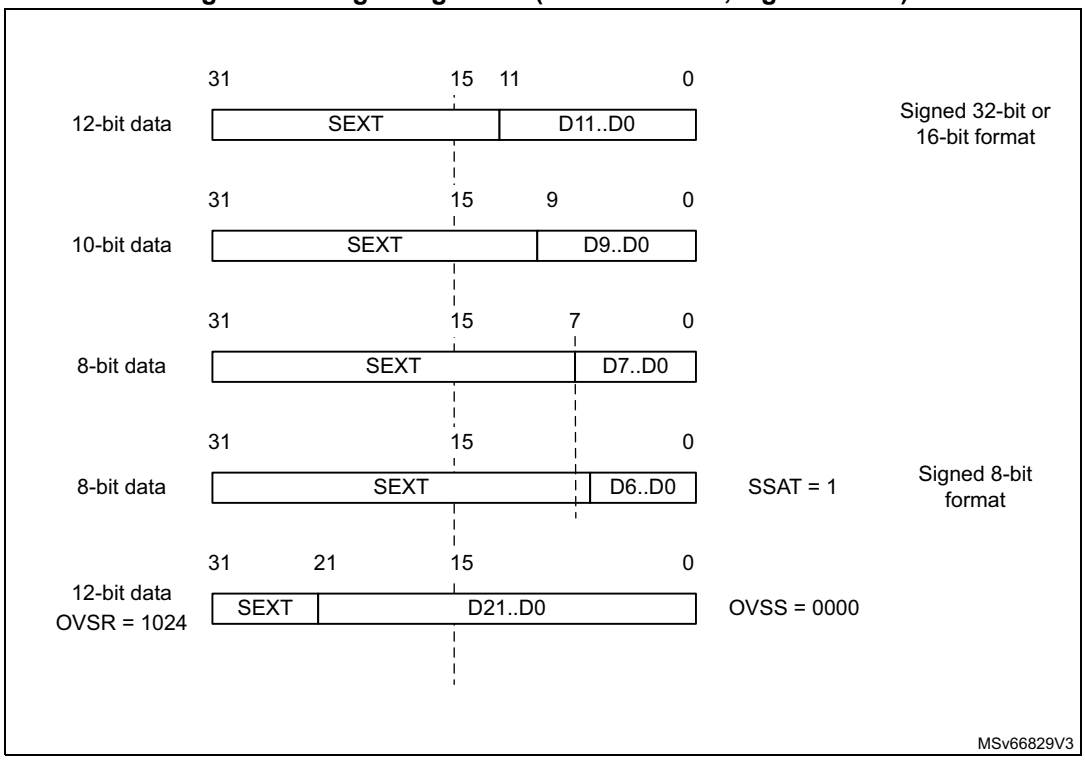

Figure 150. Left alignment (offset disabled, unsigned value)

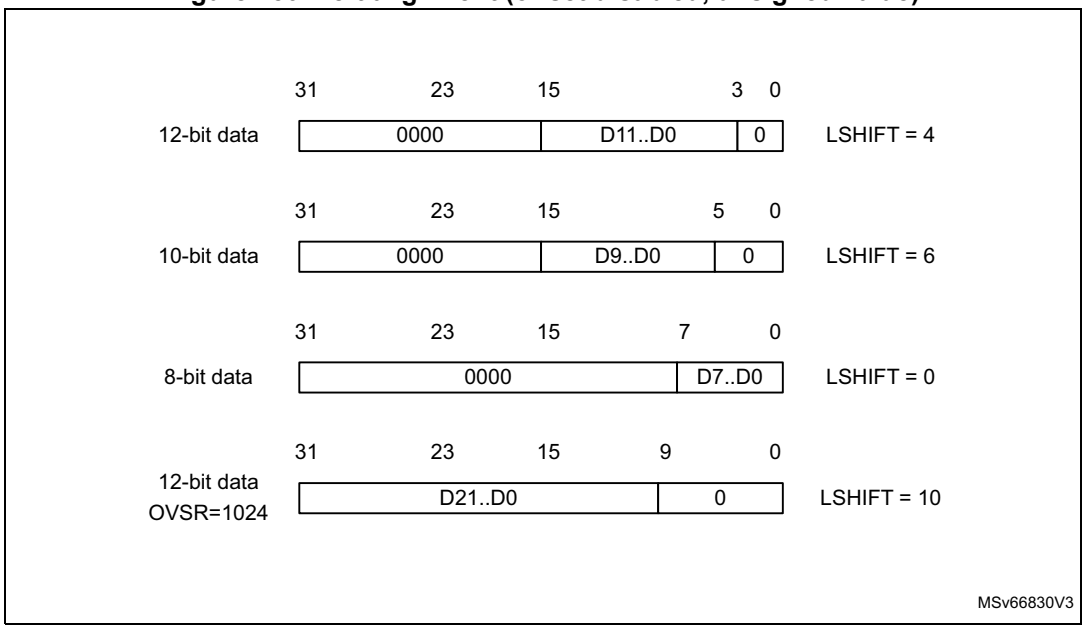

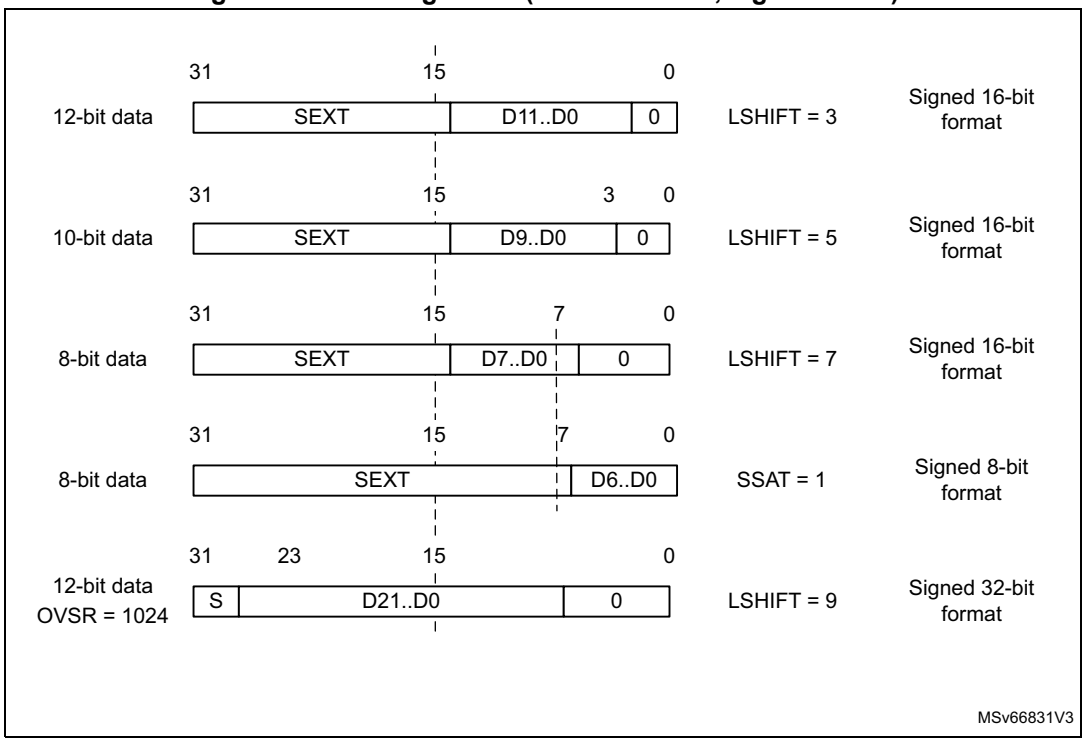

Figure 151. Left alignment (offset enabled, signed value)

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data.

To limit the original data width, the data saturation can be enabled through the SSAT and USAT bits of the ADC_OFCFGRy register.

Unsigned 12-bit data can be extended to 13-bit signed data by using an offset value different from 0x800.

The original data width can be preserved by setting SSAT bit to limit the data width to 12 bits.

Unsigned data can be saturated to the original data width by setting the USAT bit.

Table 183 shows the sign-extended data format corresponding to different resolutions.

Table 183.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	0	Sign-extended 13-bit significant data: SEXT[31:13] DATA[12:0]	0x0000 07FF - 0xFFFF F800
1	0	Sign-extended 12-bit significant data: SEXT[31:12] DATA[11:0]	0x7FF - 0x800

Table 183.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	1	Unsigned saturation 12-bit signification data: DATA[11:0]	0xFFF - 0x000
1	1	Reserved	-

Table 184 provides numerical examples for four different offset values.

Table 184. Numerical examples for 32-bit or 16-bit format

Raw conversion result	Offset value	Result SSAT = 0 USAT = 0	Result SSAT = 0 USAT = 1	Result SSAT = 1 USAT = 0
0xFFF	0x800	0x0000 07FF	0x07FF	0x07FF
0x800		0x0000 0000	0x0000	0x0000
0x000		0xFFFF F800	0x0000	0xF800
0xFFF	0x820	0x0000 07DF	0x07DF	0x07DF
0x800		0xFFFF FFE0	0x0000	0xFFE0
0x000		0xFFFF F7E0	0x0000	0xF7E0
0xFFF	0x7E0	0x0000 081F	0x081F	0x07FF
0x800		0x0000 0020	0x0020	0x0020
0x000		0xFFFF F820	0x0000	0xF820
0xFFF	0x020	0x0000 0FDF	0x0FDF	0x0FDF
0x800		0x0000 07E0	0x07E0	0x07E0
0x000		0xFFFF FFE0	0x0000	0xFFE0

Caution: SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure that this condition is respected.

Gain compensation

When the GCOMP bit is set in the ADC_GCOMP register, the gain compensation is activated on all the converted data. After each conversion, data is calculated using the following formula.

$$DATA = DATA(\text{adc result}) \times (GCOMPCOEFF) / 4096$$

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATAx or JDATAx bitfields, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used in oversampling mode, the gain calculation is performed after the accumulation and

right-shift operations to minimize the power consumption (the gain calculation is done only once and not at each conversion).

The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode, the ROVSM bit of the ADC_CFGR2 register must be set to resume the pending conversion with the correct value.

When the gain compensation is activated, the ADC conversion latency is increased by one clock cycle. In continuous and scan conversion modes, the ADC conversion rate does not change.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) issues a notification that the regular converted data has not been read (by the CPU or the DMA) before the ADC_DR FIFO (eight stages) is overflowed, or adc_hclk clock is too slow to manage the data.

The OVR flag is set when a new conversion completes while ADC_DR register FIFO was full. An interrupt is generated if the OVRIE bit is set.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP. The OVR flag is cleared by software by programming it to 1.

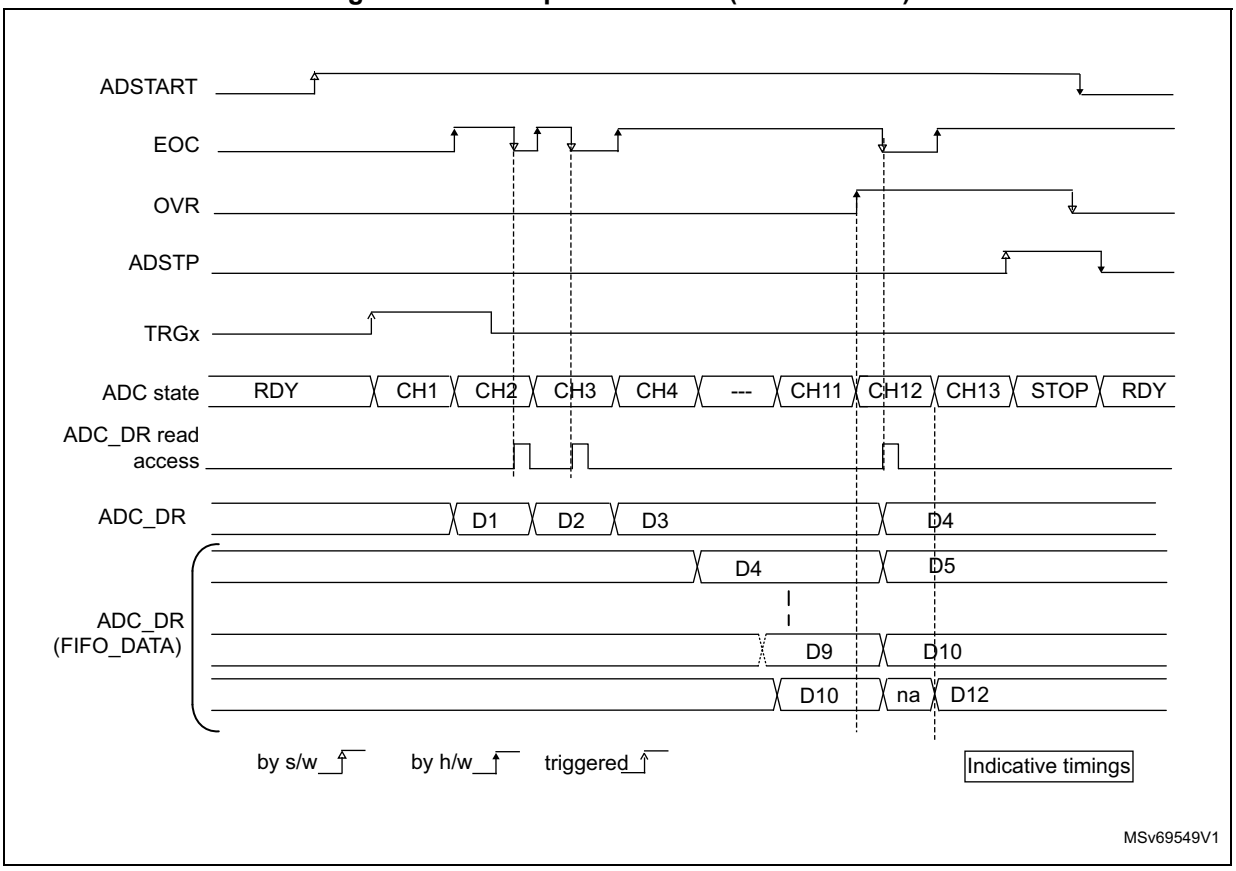
Data can be configured to be preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data are maintained up to ADC_DR FIFO depth (eight data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data is also discarded.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data. In this mode, DMA burst mode nor ADF output mode cannot be supported.

Figure 152. Example of overrun (OVRMOD = 0)



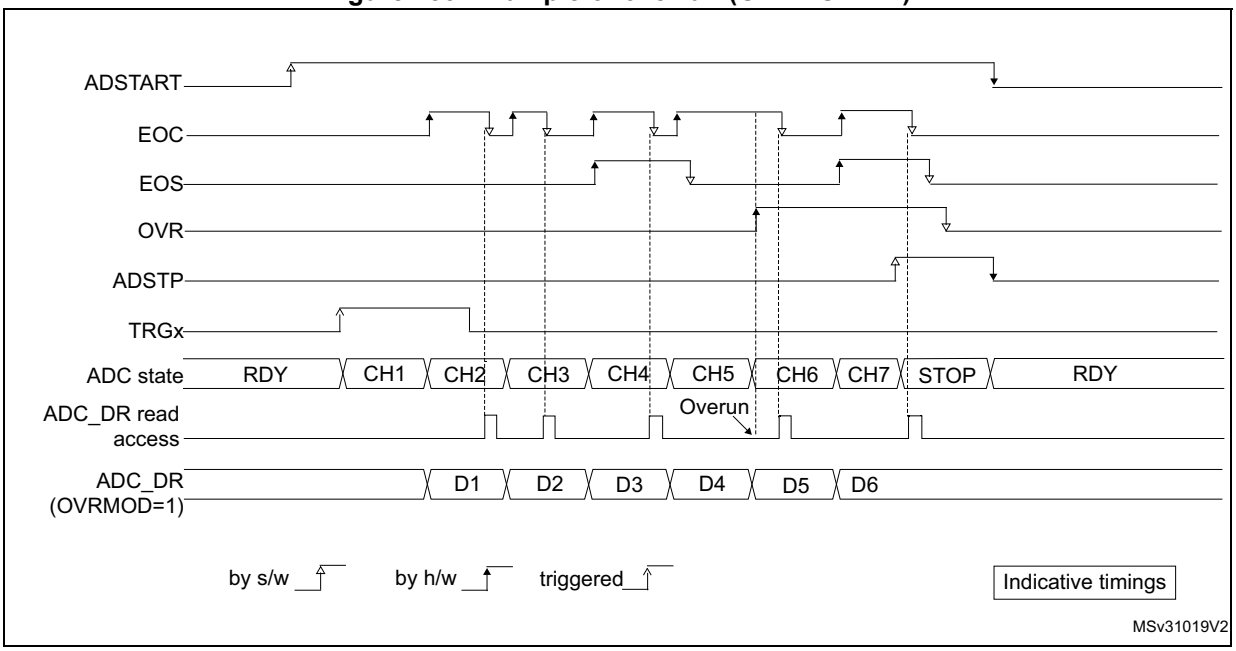


Figure 153. Example of overrun (OVRMOD = 1)

Note: Even if overrun may occur for injected channels, there is no overrun detection on these channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR1 register in single ADC mode or DAMDF different from 00 in dual ADC mode), a DMA request is generated after each channel conversion. This allows the transfer of the converted data from the ADC_DR register to the destination location configured in the DMA.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA, which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of the OVRMOD bit, the data are either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*). If OVRMOD = 0 (data preserved), DMA transfer requests are blocked.

Two different DMA modes are proposed depending on the application usage. They can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register in single ADC mode and the DAMDF bit of the ADCC12_CCR register in dual ADC mode, respectively:

- DMA one-shot mode (DMNGT[1:0] = 01)

  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT[1:0] = 11)

  This mode is suitable when programming the DMA in circular mode.

DMA one-shot mode (DMNGT[1:0] = 01)

In one-shot mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (that is when DMA_LACK interrupt occurs, see *Direct-memory controller* section) even if a new conversion has been started.

When DMA transfers are complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen,
- All ongoing conversions are aborted with the partial result discarded,
- No new DMA request is issued to the DMA controller in order to avoid generating an overrun error if there are still conversions that are started,
- The scan sequence is stopped and reset, and
- The DMA is stopped.

DMA circular mode (DMNGT[1:0] = 11)

In circular mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows the configuration of the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. The DMA can be programmed either in single-transfer mode or in burst mode (four beats). The appropriate request line is selected by the DMA according to the mode selected. Refer to *Section Direct memory access controller* for further information.

Due to the existence of FIFO, DMA requests are generated until the FIFO is emptied. To stop DMA requests even when the FIFO is not emptied, set the ADSTP bit.

22.4.27 Managing conversions using the ADF

The ADC conversion results can be transferred directly to the ADF.

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers the 16 least significant bits of the regular data register to the ADF through adcx_dat[15:0] bus, which in turn resets the EOC flag once the transfer is effective.

The data format must be in 16-bit signed format:

ADC_DR[31:16] = Don’t care

ADC_DR[15] = Sign

ADC_DR[14:0] = Data

Any value above the 16-bit signed format is truncated.

To obtain a 16-bit signed format, the OFFSET function needs to be activated.

In this mode, OVRMOD = 1 is not supported.

22.4.28 Dynamic low-power features

Autodelayed conversion mode (AUTDLY)

The ADC implements an autodelayed conversion mode controlled by the AUTDLY configuration bit. Autodelayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

Regular conversion mode

When AUTDLY is set, a new conversion can start if the following conditions are met:

- All the previous data of the same group have been treated, and
- The ADC_DR register has been read or the EOC bit has been cleared (see *Figure 154*).

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

The delay is inserted after each regular conversion.

Injected conversion mode

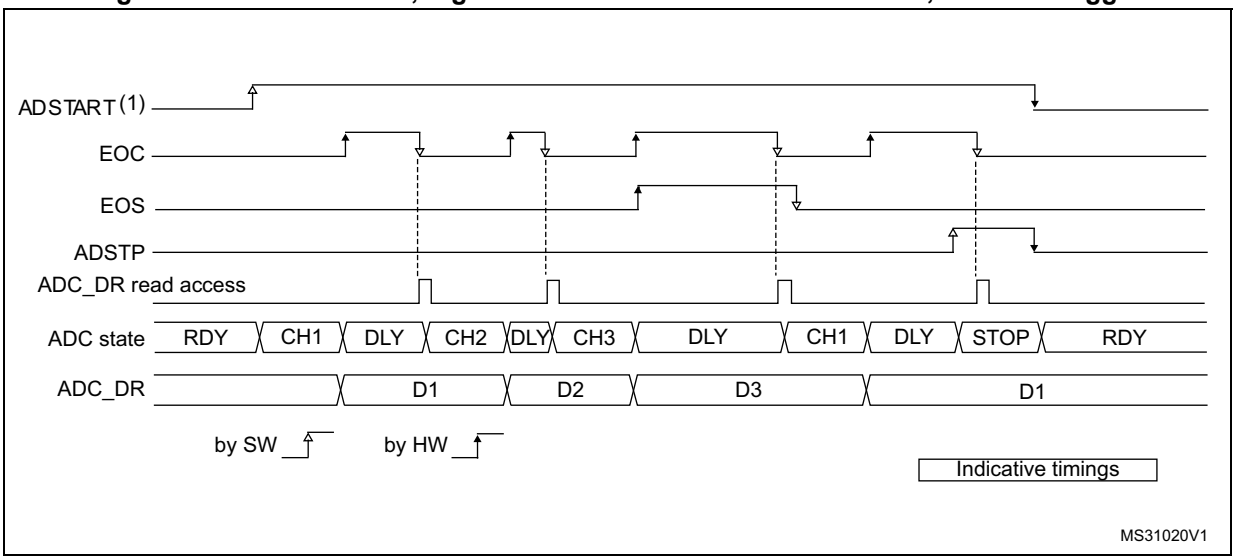
When AUTDLY is set, a new conversion can start only if the JEOS bit has been cleared (see *Figure 155*). Since there are four ADC_JDRy registers, the autodelay is performed at the end on the injected conversion sequence.

There is no delay inserted between each conversion of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored. This is not the case for software triggers for which the ADSTART and JADSTART bits can still be set during the autodelay to restart the conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

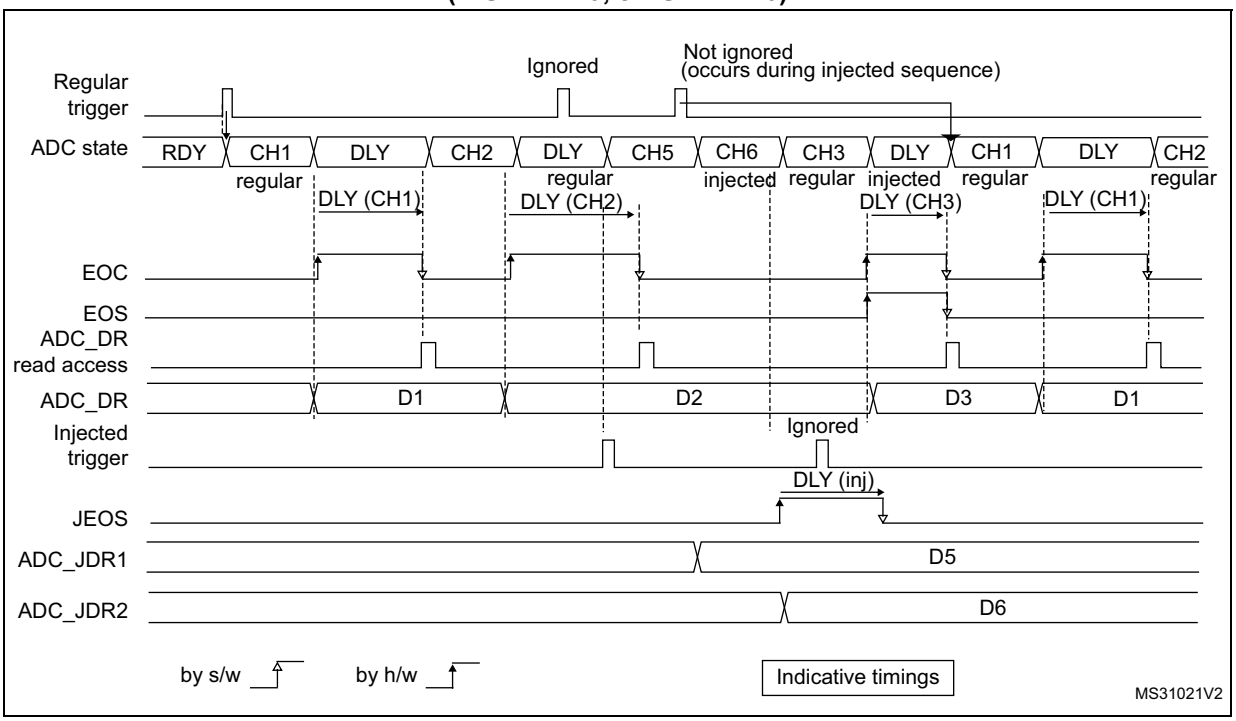
- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 155*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 157*).



The behavior is slightly different in autoinjection mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 158*).

Caution: In autoinjection mode, there is no delay between the last regular conversion and the first injected conversion. The user must clear the last EOC flag before clearing the JEOS flag, otherwise the next sequence might start before EOC flag is cleared.

In autodelay mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.



In autodelay mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

22.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 159. Analog watchdog guarded area

AWDy flag and interrupt

An interrupt can be enabled for each of the three analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it, or by setting ADDIS.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in scan mode is not allowed), a valid ADC conversion data range can be configured through the ADC_AWD1LTR and ADC_AWD1HTR registers. When the conversion results have consecutively passed the threshold for more than the watchdog filter value (AWDFILT[2:0] + 1), AWD1_OUT is generated as well as the AWD1 flag. Before this value is reached, AWD1 output is not activated.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 185 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

Table 185. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog flag is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed through HTR[22:0] bits of the ADC_AWD1HTR register and LTR[22:0] bits of the ADC_AWD1LTR register for the analog watchdog 1.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024, offset and gain compensation)

When converting data with a resolution of less than 12 bits (defined by RES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data.

Table 186 describes how the comparison is performed for all the possible resolutions and for analog watchdog 1.

Table 186. Analog watchdog 1, 2, 3 comparison

Resolution (RES[1:0] bits)	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds

11: 6-bit	DATA[11:6],000000	LTR[22:0] and HTR[22:0]	The user must configure LTR[5:0] to 0b000000 and HTR[5:0] to 0b000000.

1. Refer to *Section : Gain compensation* for additional details on analog watchdog comparison.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCH[18:0] (of ADC_AWD2CR and ADC_AWD3CR).

The corresponding watchdog is enabled when any bit of AWDCH[18:0] (of ADC_AWD2CR and ADC_AWD3CR) is set.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024 and offset compensation in signed format with gain compensation) and is programmed through the ADC_AWD2HTR, ADC_AWD2LTR, ADC_AWD3HTR and ADC_AWD3LTR registers.

When converting data with a resolution of less than 12 bits (defined by RES[1:0]) bits), the LSBs of the programmed threshold must be kept cleared, the internal comparison being performed on the full 12-bits converted data (left aligned).

ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated with an internal hardware signal ADC_AWDy_OUT (*y* being the watchdog number), which is directly connected to the ETR input (external trigger) of some of the on-chip timers. Refer to the on-chip timers sections to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion that is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS). Note that stopping regular or injected conversions (by setting ADSTP or JADSTP) has no influence on the generation of ADCx_AWDy_OUT.

Note: The AWDy flag is set by hardware and reset by software: the AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADC_AWDy_OUT can toggle while the AWDy flag remains at 1 if the software did not clear the flag).

The AWDy flag is cleared by programming it to 1 or by set ADDIS bit. ADSTP and JADSTP bits do not reset the AWDy flag.

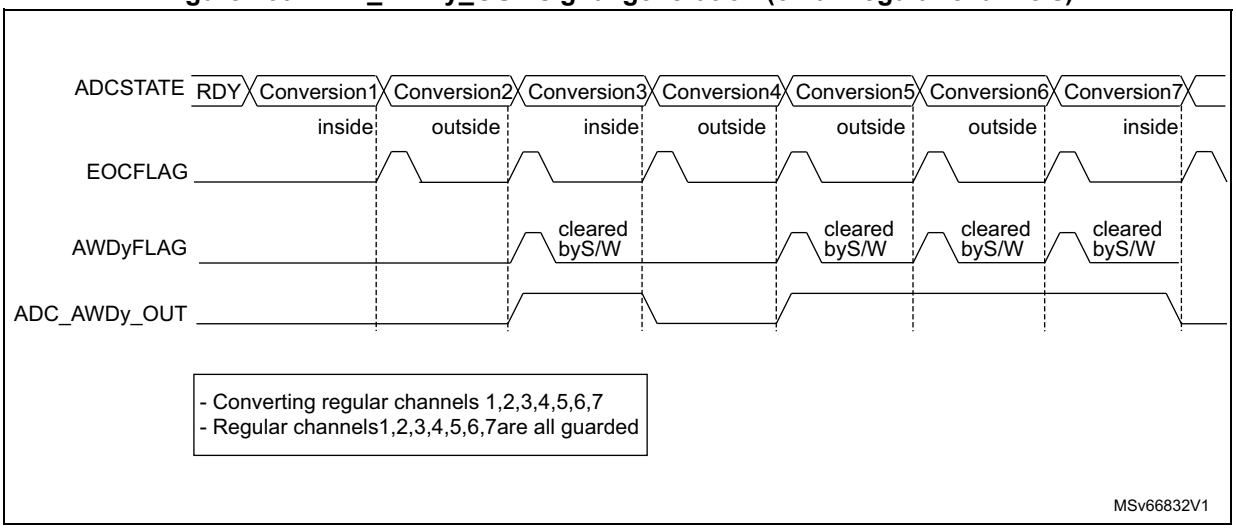

Figure 161. ADC_AWDy_OUT signal generation (AWDy flag not cleared by software)

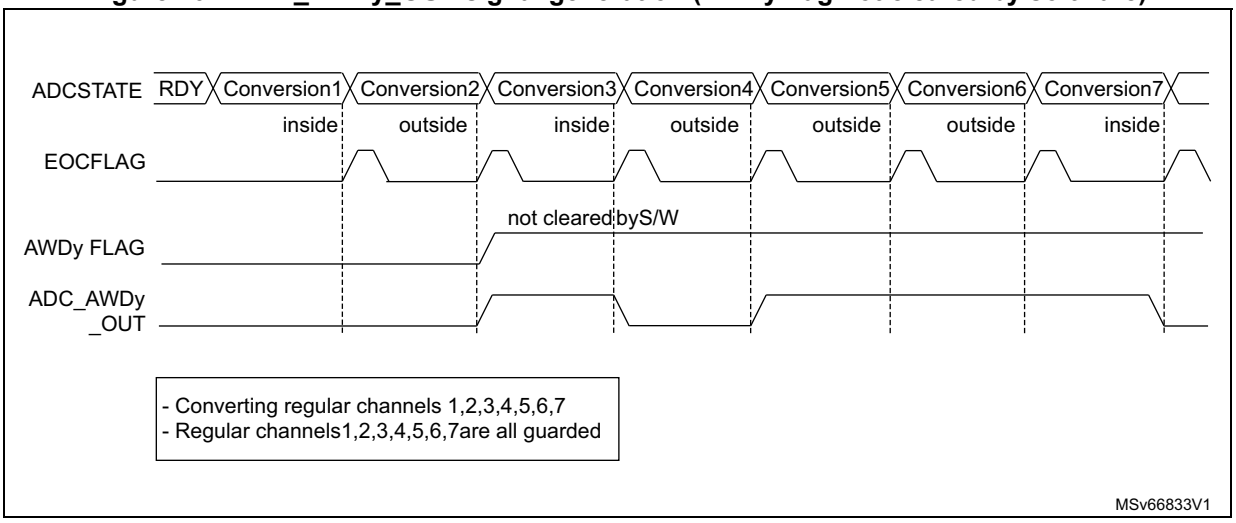

Figure 162. ADC_AWDy_OUT signal generation (on a single regular channel)

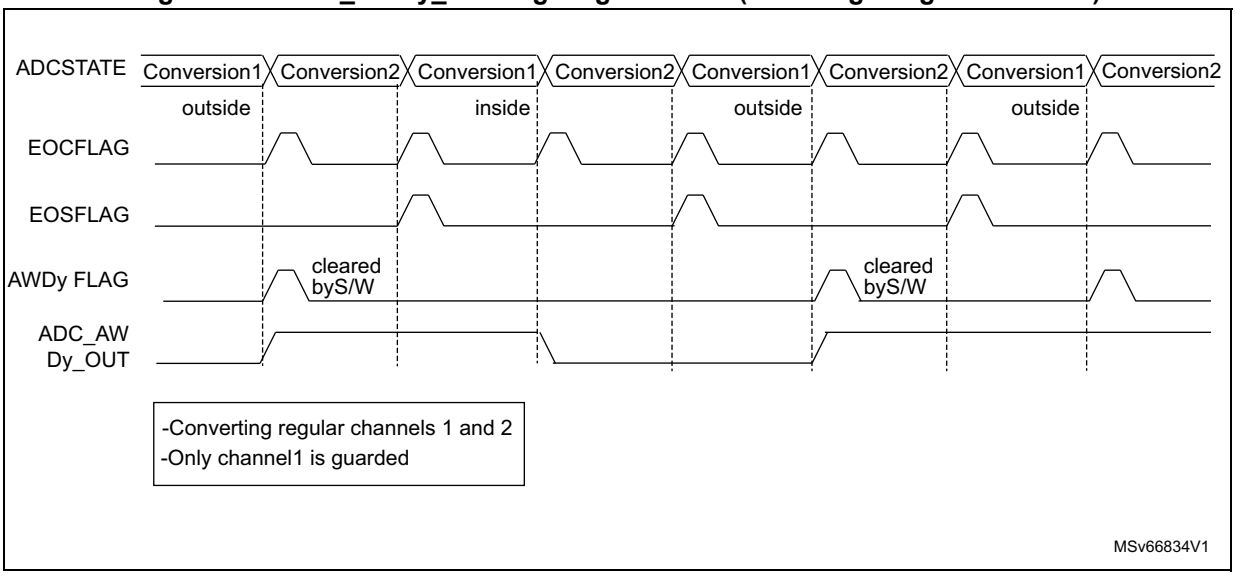

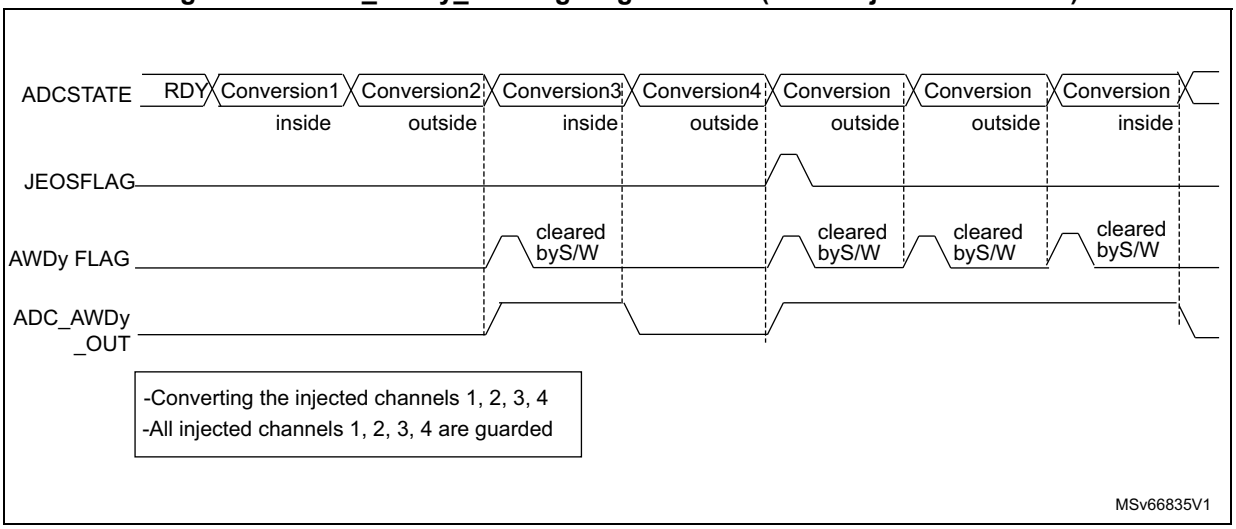

Figure 163. ADC_AWDy_OUT signal generation (on all injected channels)

Analog watchdog threshold control

LTR[22:0] and HTR[22:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTR[22:0] and HTR[22:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new modified threshold, no interrupt and AWDy_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion that started after the threshold update. If AWDy_OUT is already asserted, programming the new thresholds does not deassert the AWDy_OUT signal. However, the watchdog threshold must not be changed twice during the four adc_ker_ck periods.

Analog watchdog with gain and offset compensation

When the gain and offset compensation are enabled, the analog watchdog compares the data after the compensation.

22.4.30 Oversampler

The oversampling unit performs data preprocessing to offload the device. It is able to handle multiple conversions and average them into a single data with increased data width, up to 22-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement and basic filtering.

The oversampling ratio N is defined through the OVSR[9:0] bits of the ADC_CFGR2 register. They can range from 2x to 1024x. The division coefficient *M* consists of a right bit shift up to 10 bits. It is defined through the OVSS[3:0] bits of the ADC_CFGR2 register.

The summation unit can yield a result up to 22 bits, which can be left or right shifted. When the right shift is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred to the ADC_DR data register.

Figure 164 gives a numerical example of the processing, from a raw 22-bit accumulated data to the final 12-bit result.

Figure 164. 12-bit result oversampling with 10-bit right shift and rounding

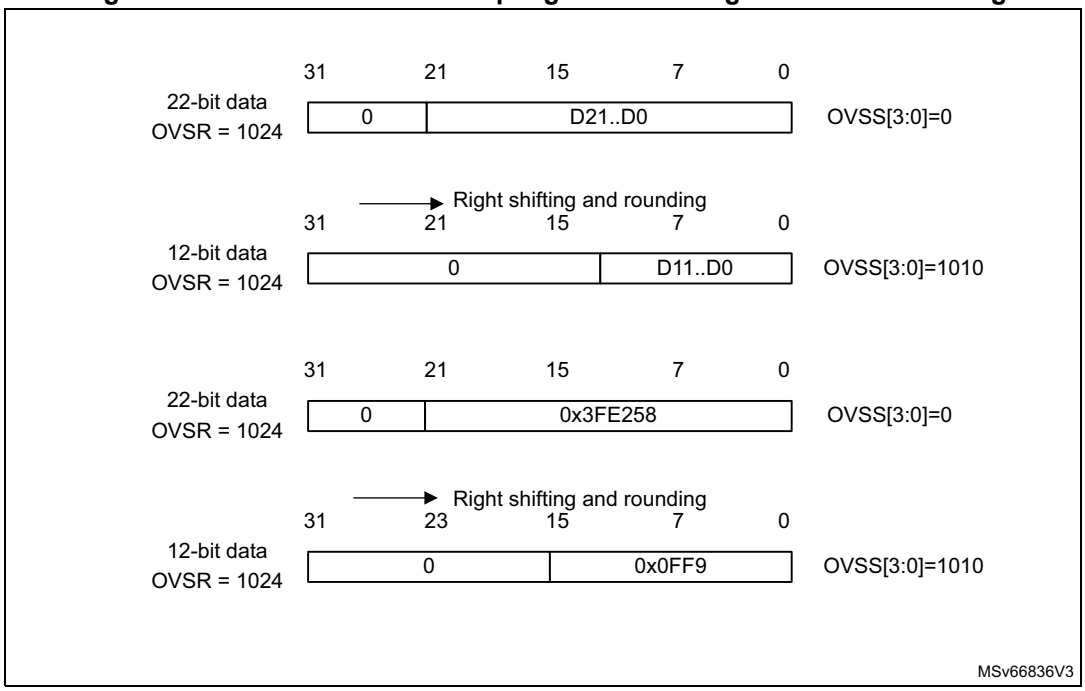

Table 152 gives data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 187. Maximum output results versus N and M

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS =0111	8-bit shift OVSS = 1000

The conversion timing rate does not change in oversampling mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversion, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase.
- The end of conversion (EOC) occurs once every N conversion, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after a total of N x sequence length conversions).

Unlike the conversion rate, the conversion latency changes in oversampling mode: each single conversion introduces an additional accumulation. As a result, an additional clock cycle is required when all the conversions are complete, after the accumulation and right-shift. The EOC flag is set two additional clock cycles after the conversion is complete.

ADC operating modes supported in oversampling mode (single ADC mode)

In oversampling mode, most of the ADC operating modes are maintained:

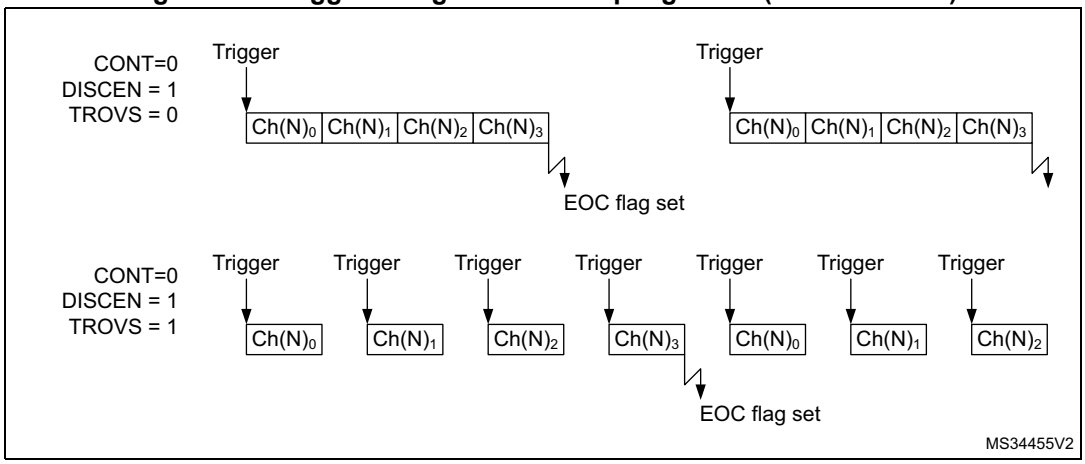
- Single or continuous conversion modes
- ADC conversions started either by software or triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits of the ADC_CFGR1 register) are accumulated, truncated, rounded, and shifted in the same way as 12-bit conversions are.

Analog watchdog

The analog watchdog functionality is maintained, with the following differences:

- The RES[1:0] bits are ignored and the comparison is always done using the full 23-bit values HTR[22:0] and LTR[22:0].
- The comparison is performed on the oversampled accumulated value before shifting.

Triggered mode



The oversampling can also be used for basic filtering purpose. Although it not a very powerful filter (slow roll-off and limited stop band attenuation), it can act as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched-mode power supply). For this purpose, a specific discontinuous mode can be enabled through the TROVS bit in ADC_CFGR2, to be able to achieve an oversampling frequency defined by the user and independent from the conversion time itself. The TROVS bit is supported with hardware trigger mode.

Figure 165 shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

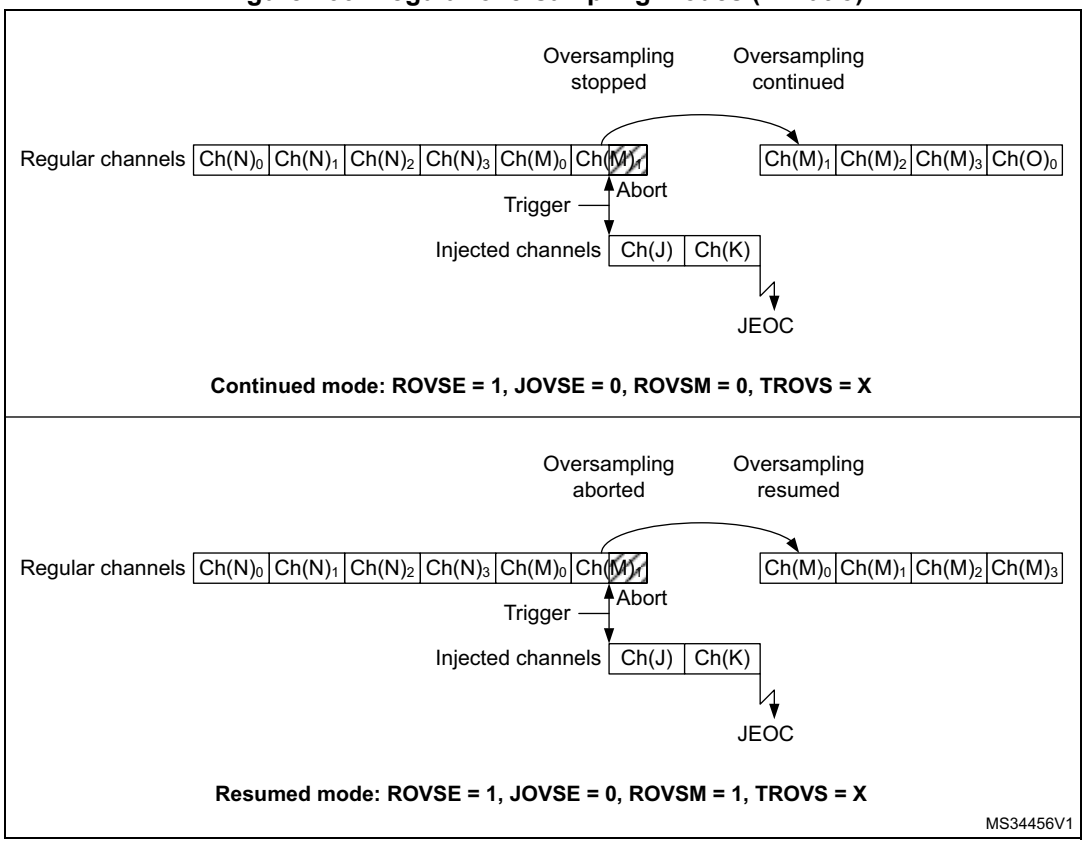
If the TROVS bit is set, neither JAUTO nor AUTODLY is supported.

Figure 165. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management in oversampling mode

In oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only



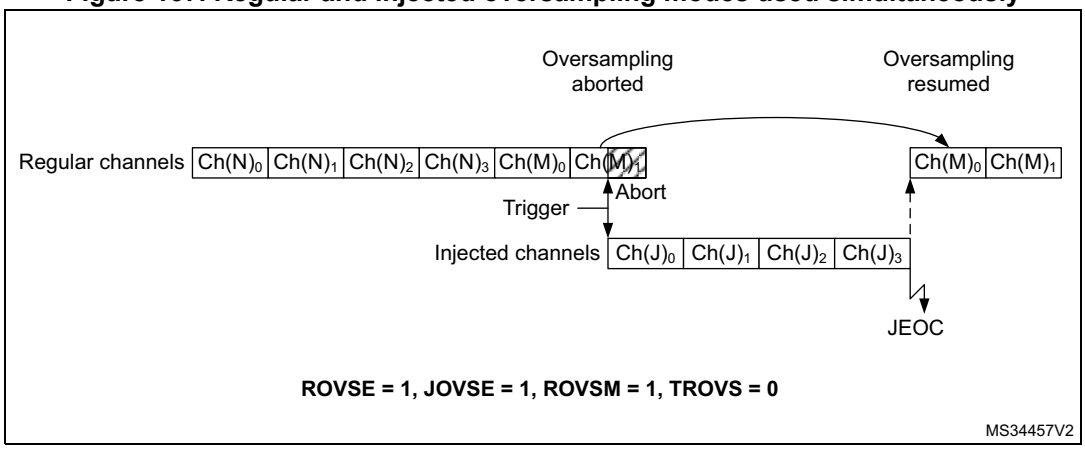
The regular oversampling mode ROVSM bit defines how the regular oversampling sequence is resumed if it is interrupted by an injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is

complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);

- In resumed mode, the accumulation restarts from 0 (previous conversion results are ignored). This mode guarantees that all the data used for oversampling were converted back-to-back within a single time slot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequence is blocked.
- *Figure 166* gives examples for a 4x oversampling ratio.

Figure 166. Regular oversampling modes (4x ratio)



Oversampling injected channels only

The injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling must be resumed (ROVSM bit = 1), as shown in *Figure 167*.

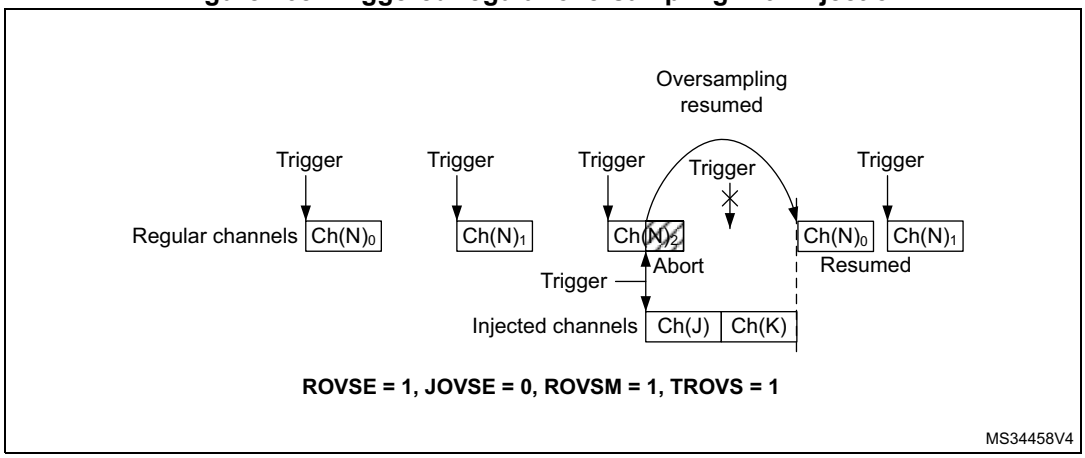


Figure 167. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled and the ROVSM bit set (Resumed mode is forced). The JOVSE bit must be reset. The behavior is shown in *Figure 168*.

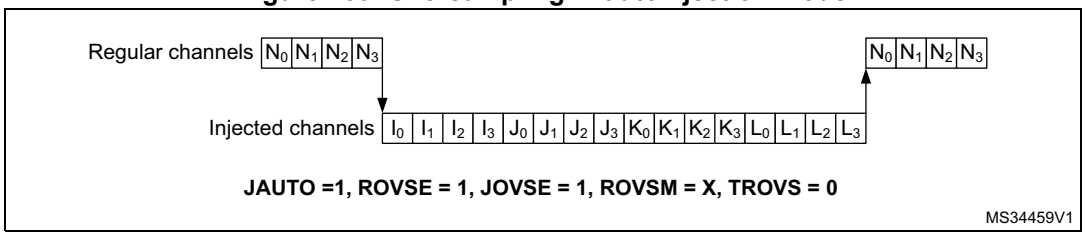

Figure 168. Triggered regular oversampling with injection

Autoinjection mode

It is possible to oversample autoinjected sequences and store all conversion results in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in autoinjection mode. *Figure 169* shows how the conversions are sequenced.

Figure 169. Oversampling in autoinjection mode

In addition, the triggered mode can be enabled using the TROVS bit. In this case, the ADC must be configured as follows: JAUTO = 1, DISCEN = 0, JDISCEN = 0, DISCNUM = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Combined modes summary

Table 188 summarizes all combinations, including the modes that are not supported.

Table 188. Oversampler operating mode summary

Regular oversampling ROVSE	Injected oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode

1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

22.4.31 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see *Figure 170*).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADC master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCC_CCR register.

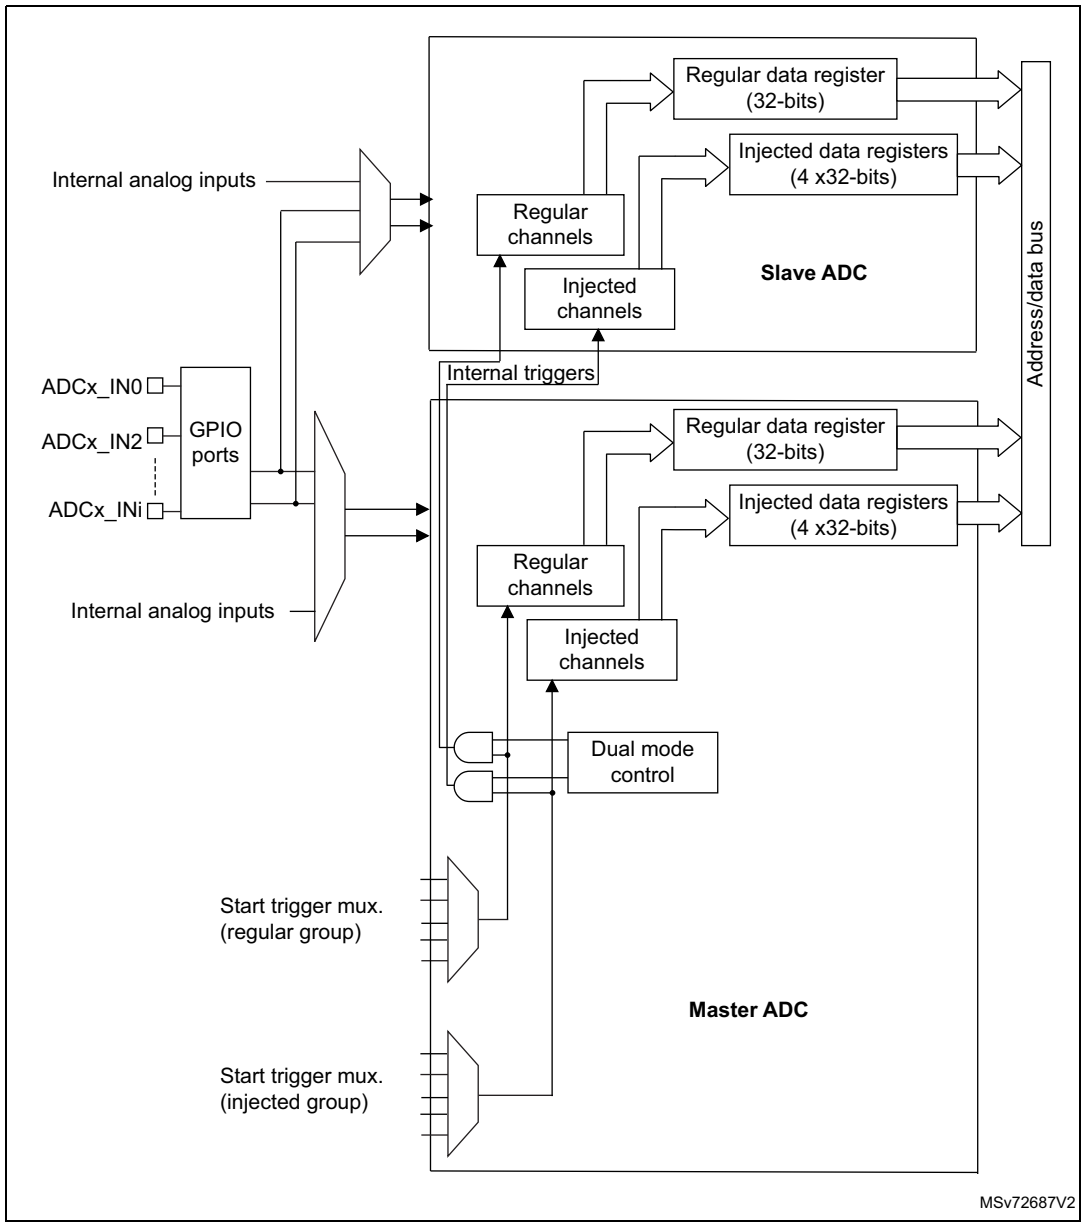
Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when DUAL[4:0] bits in the ADCC_CCR register are not equal to zero), the CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JAUTO bits of the ADC_CFGR1 register are shared between the master and slave ADC: the slave ADC bits are ignored and always apply to the corresponding bits of the master ADC.



To start a conversion in dual mode, the user must program the EXTEN[1:0], EXTSEL, JEXTEN[1:0] and JEXTSEL bits of the master ADC only to configure a software or hardware trigger and a regular or injected trigger (the EXTEN[1:0] and JEXTEN[1:0] bits of the slave ADC are don't care).

In regular simultaneous or interleaved modes, once the user sets the ADSTART or ADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, ADSTART or ADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes, once the user sets the JADSTART or JADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, JADSTART or JADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCC_CDR). The flags can also be read in parallel by reading the dual-mode status register (ADCC_CSR).

Figure 170. Dual ADC block diagram

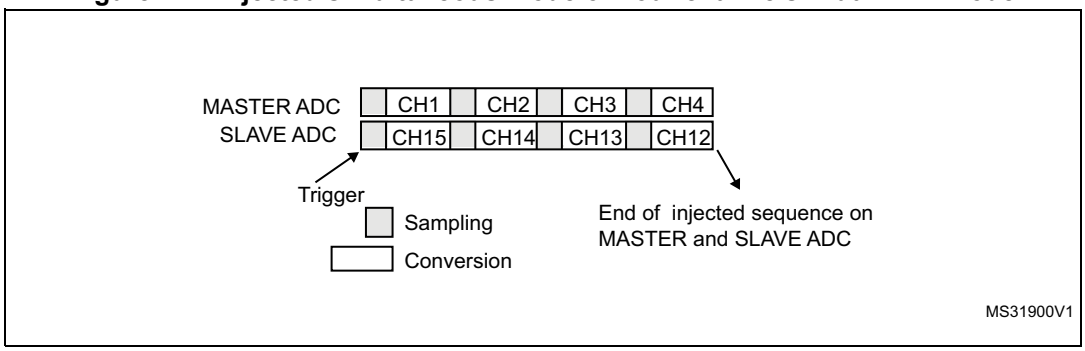
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCC_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode

The injected simultaneous mode is selected by programming DUAL[4:0] bits to 0b00101.

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).



In simultaneous mode, the user software must convert sequences with the same length.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

The software is notified by interrupts when it can read the data:

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master-injected sequence is equal to the duration of the slave injected one (as shown in *Figure 171*), the software can enable only one of the two JEOS interrupts (for example the master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 171. Injected simultaneous mode on four channels: Dual ADC mode

If JDISCEN is set, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with the AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored.
  There is the same behavior for regular sequences occurring on the slave ADC.

Regular simultaneous mode with independent injected conversions

The regular simultaneous mode is selected by programming DUAL[4:0] bits to 0b00110.

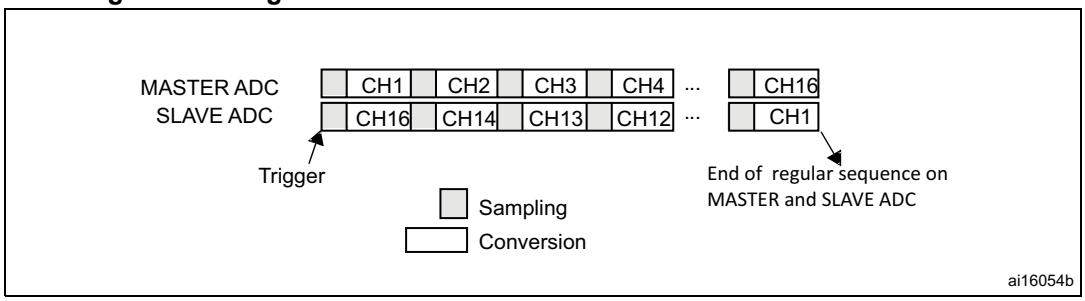
This mode applies to a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR1 register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on the master or on the slave) aborts the current simultaneous conversions both for master and slave. They are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, the user software must convert sequences with the same length.

The software is notified by interrupts when it can read the data:



- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (as shown in *Figure 172*), the software can enable only one of the two EOC interrupts (for example the master EOC) and read both converted data from the common data register (ADCC_CDR).

The regular data can also be read using the DMA. Several methods are possible:

- Use two DMA channels (one for the master and one for the slave). In this case DAMDF[1:0] bits must be kept cleared:
- Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
- Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configure the dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  a) Set DAMDF[1:0] = 0b10 or 0b11 (depending on resolution).
  b) A single DMA channel is used (the one corresponding to the master). Configure the DMA master ADC channel to read the common ADC register (ADCC_CDR).
  c) A single DMA request is generated each time both master and slave EOC events occur. At that time, the slave ADC converted data are available in the upper half-word of the ADCC_CDR 32-bit register and the master ADC converted data available in the lower half-word of the ADCC_CDR register.
  d) Both EOC flags are cleared when the DMA reads the ADCC_CDR register.

Note: When DAMDF[1:0] = 0b10 or 0b11, the user must program the same number of conversions in the master and in the slave sequence. Otherwise, the remaining conversions do not generate a DMA request.

Figure 172. Regular simultaneous mode on 16 channels: dual ADC mode

If the DISCEN bit is set, each "*n*" simultaneous conversion of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with the AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence starts only if the common data register (ADCC_CDR) (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCC_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

The DMA can be used to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master sequence is equal to the number of conversions in the slave sequence.
- For each simultaneous conversion of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert, the sampling time and the resolution of each channel.

Note: This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

Interleaved mode with independent injected conversions

This mode is selected by programming DUAL[4:0] bits to 0b00111.

It can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately,
- The slave ADC starts after a delay of several ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay between two conversions in interleaved mode is configured in the DELAY bits in the ADCC_CCR register (see *Table DELAY bits versus ADC resolution*). This delay starts counting one half cycle after the end of the sampling phase of the master

conversion. This way, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However, the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: In case of 16-bit data format, only the EOC interrupt of the slave can be enabled and the common data register (ADCC_CDR) can be read. For 32-bit data format, enable both the slave and master EOC interrupts and the ADCC_CDR2 register. However, in this case, the user must make sure that the durations of the conversions are compatible to ensure that, inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the DAMDF mode.

Regular data can also be transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the DAMDF mode, as described below:

1. Configure DAMDF[1:0] = 0b10 or 0b11 (depending on resolution).
2. A single DMA channel is used (the one of the masters). Configure the DMA master ADC channel to read the common ADC register (ADCC_CDR).
3. A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of the ADCC_CDR register.
4. Both EOC flags are cleared when the DMA reads the ADCC_CDR register.

Table 189. DELAY bits versus ADC resolution(1)

DELAY bits	12-bit resolution	10-bit resolution	8-bit resolution	6-bit resolution
0000	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$

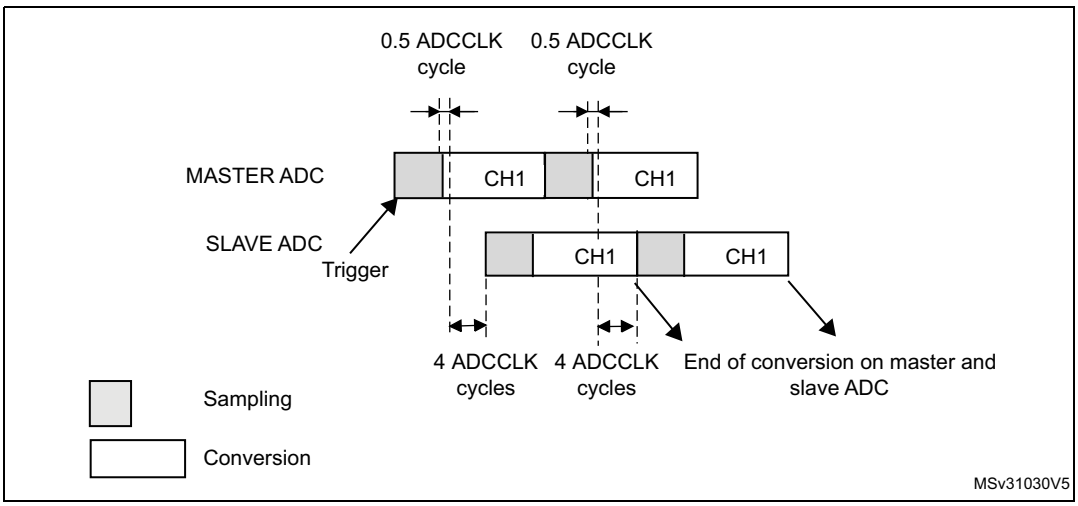
others	12 * $T_{adc_ker_ck}$	10 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$

1. Preliminary information, subject to change.

Figure 173. Interleaved mode on 1 channel in continuous conversion mode: Dual ADC mode



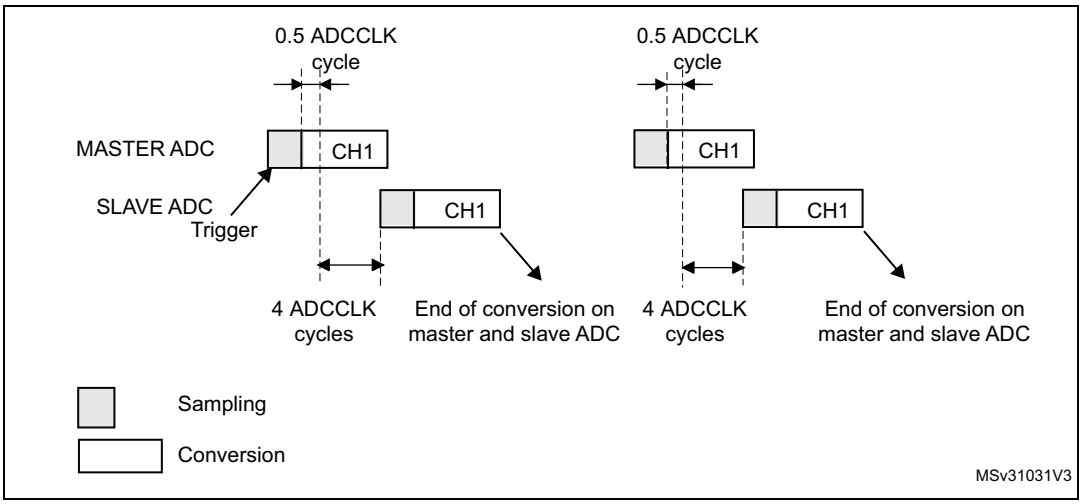


Figure 174. Interleaved mode on 1 channel in single conversion mode: Dual ADC mode

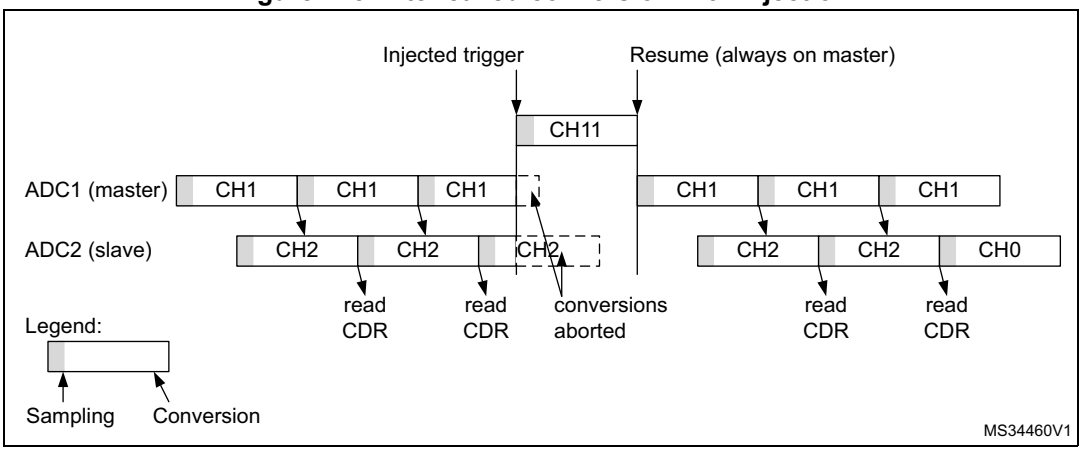


If the DISCEN bit is set, each "*n*" simultaneous conversion ("*n*" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In interleaved mode, injected conversions are supported. When injection is done (either on master or slave), both master and the slave regular conversions are aborted and the sequence is restarted from the master (see *Figure 175*).

Note: In interleaved mode, the ADCx_AWDy_OUT signal for the master ADC is synchronized with the EOC of the master ADC, but the interrupt flag is synchronized with the EOC/JEOC flag of the slave ADC.

In addition, the ROVSM = 0 setting is not supported in oversampling mode.

Figure 175. Interleaved conversion with injection

Alternate trigger mode

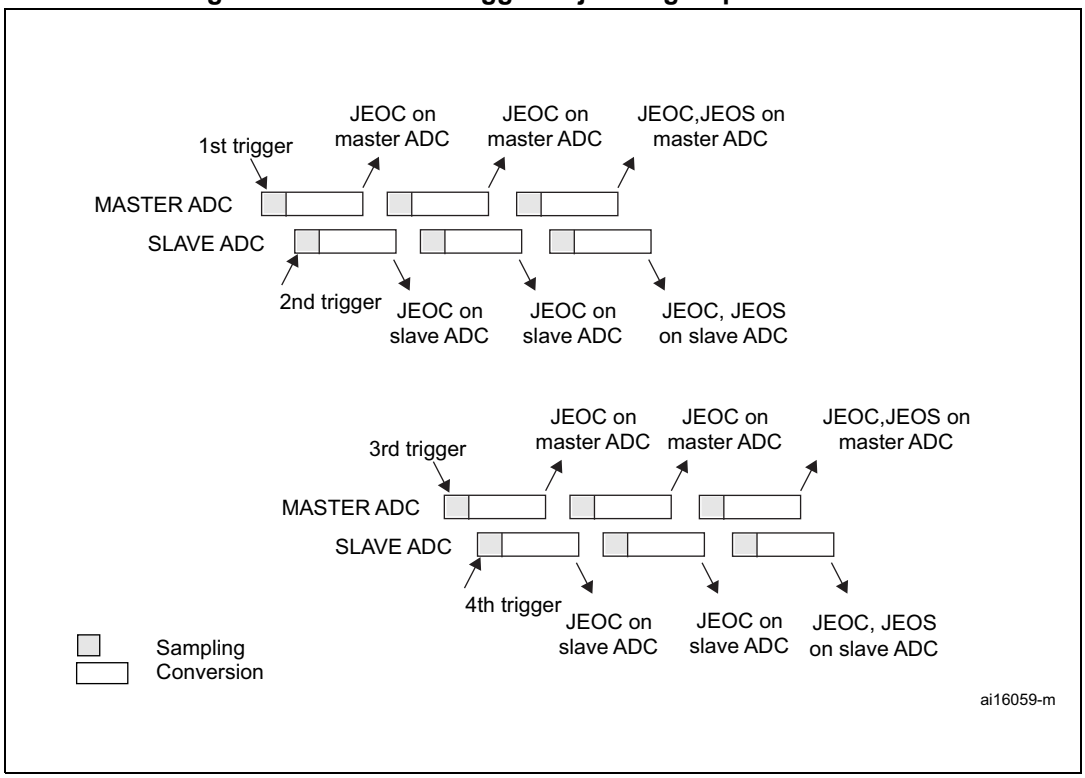
The alternate trigger mode is selected by programming DUAL[4:0] bits to 0b01001.

This mode can only be started on an injected group. The source of the external trigger comes from the multiplexer injected group of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 0x0.

Injected discontinuous mode disabled (JDISCEN=0 for both ADC)

1. When the first trigger occurs, all injected master ADC channels in the group are converted.
2. When the second trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on...



A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 176. Alternate trigger: injected group of each ADC

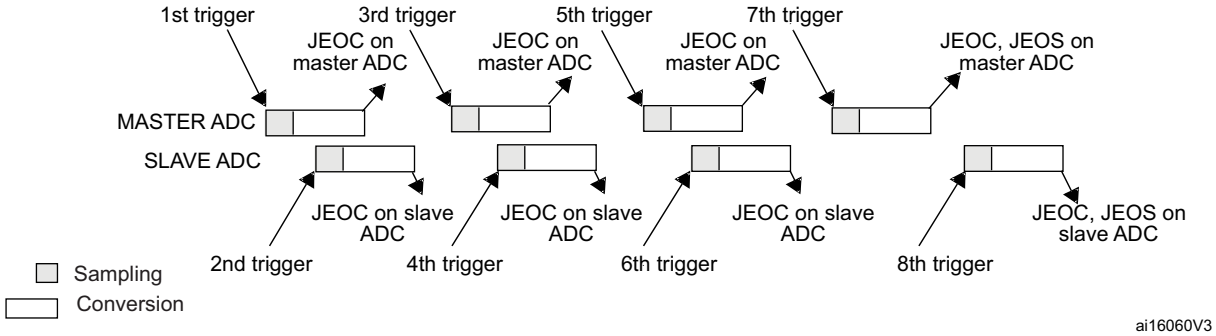
Note: Regular conversions can be enabled on one or all ADCs. In this case, the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between two trigger events must be greater than or equal to one ADC clock period. The minimum time interval between two trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

1. When the first trigger occurs, the first injected channel of the master ADC is converted.
2. When the second trigger occurs, the first injected channel of the slave ADC is converted.
3. And so on...



A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted, then the alternate trigger process restarts.

Figure 177. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode

Combined regular/injected simultaneous mode

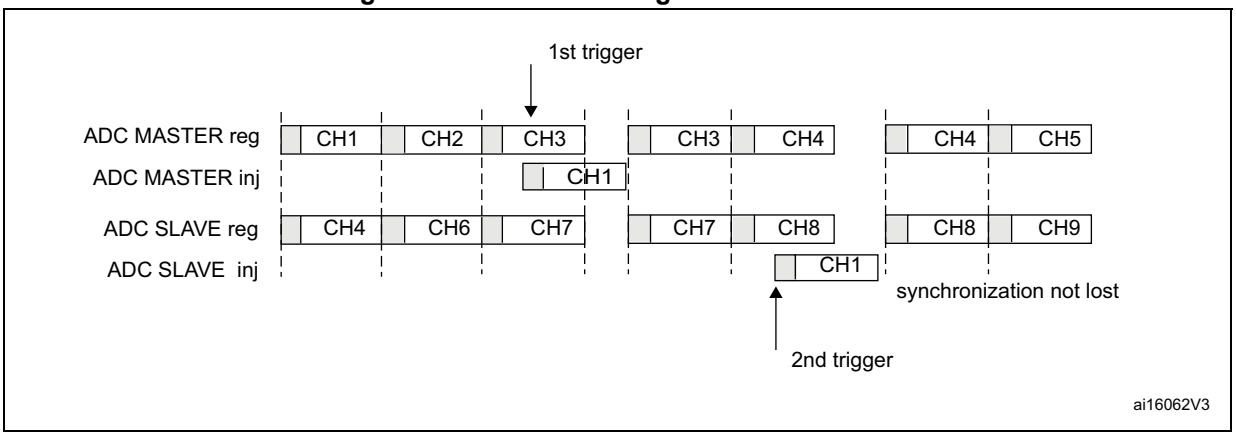
This mode is selected by programming DUAL[4:0] bits to 0b00001.

The simultaneous conversion of a regular group can be interrupted to start the simultaneous conversion of an injected group.

Note: In combined regular/injected simultaneous mode, the user software must convert sequences with the same length or ensure that the interval between triggers is longer than the sum of the conversion times of the two sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous and alternate trigger mode

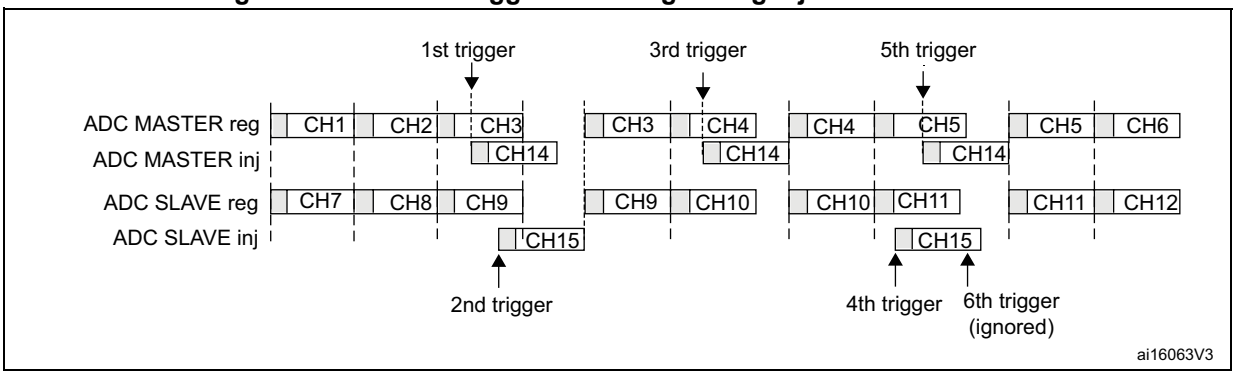
This mode is selected by programming DUAL[4:0] bits to 0b00010.



The simultaneous conversion of a regular group can be interrupted to start the alternate trigger conversion of an injected group. *Figure 178* shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion immediately starts after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

Note: In combined regular simultaneous + alternate trigger mode, the user software must convert sequences with the same length or ensure that the interval between triggers is longer than the sum of the conversion times of the two sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.



The software trigger is not supported for injected conversions.

Figure 178. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 179* shows the behavior in this case (note that the sixth trigger is ignored because the associated alternate conversion is not complete).

Figure 179. Case of trigger occurring during injected conversion

Combined injected simultaneous and interleaved mode

This mode is selected by programming DUAL[4:0] bits to 0b00011.

An interleaved conversion can be interrupted with a simultaneous injected event.

In this case, the interleaved conversion is immediately interrupted and the simultaneous injected conversion starts. At the end of the injected sequence, the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master's one. *Figure 180*, *Figure 181* and *Figure 182* show examples of this behavior.

Note: In this mode, the ROVSM =0 setting is not supported in oversampling mode.

Caution: In this mode, it is mandatory to use the common data register to read the regular data with a single read access. Otherwise, master-slave data coherency is not guaranteed.

Figure 180. Interleaved single channel CH0 with injected sequence CH11, CH12

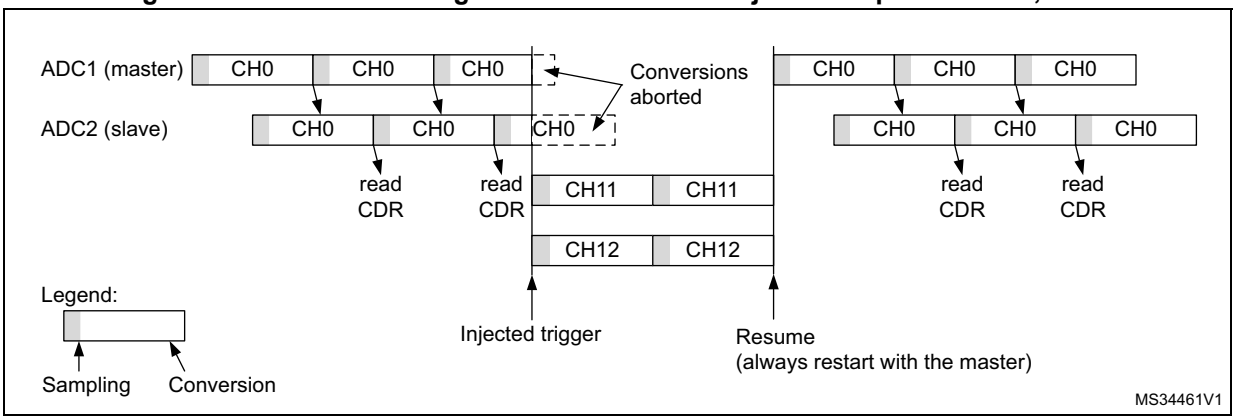


Figure 181. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 1: Master interrupted first

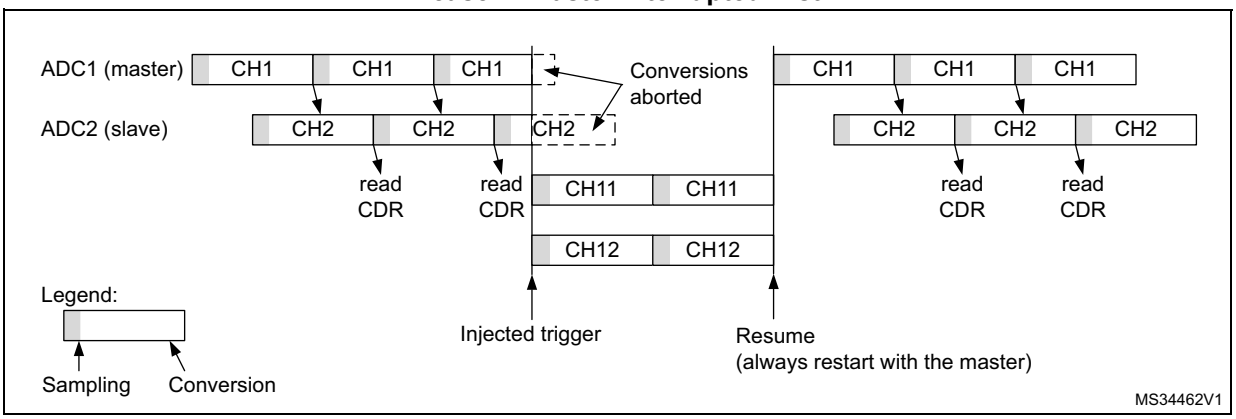

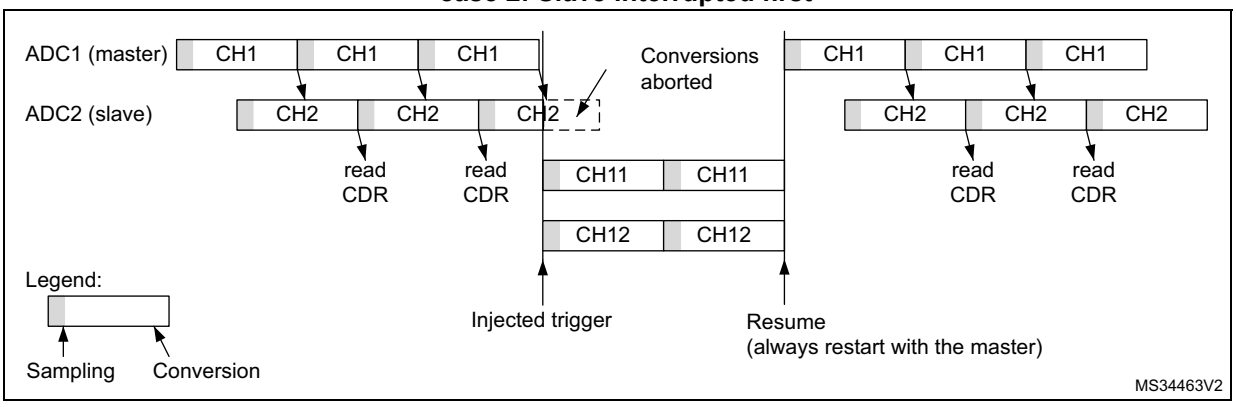

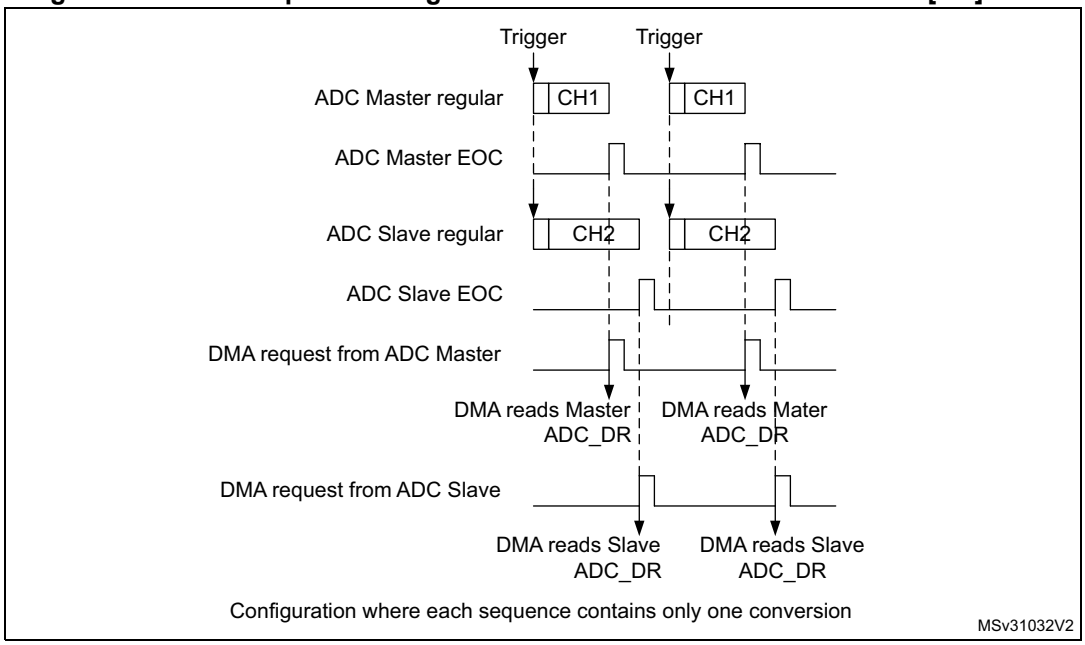

Figure 182. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 2: Slave interrupted first

DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to *Figure 183: DMA Requests in regular simultaneous mode when DAMDF[1:0]=0b00*).

Figure 183. DMA Requests in regular simultaneous mode when DAMDF[1:0]=0b00

In interleaved mode, it is also possible to save one DMA channel and transfer both data using a single DMA channel. To do this, the DAMDF[1:0] bits must be configured in the ADCC_CCR register:

- **DAMDF[1:0] = 0b10, 32-bit format:**

  A single DMA request is generated alternatively after either the master or slave EOC events have occurred. At that time, the data are alternatively available in the 32-bit register ADCC_CDR2 32-bit register.

  This mode is used in interleaved mode and in regular simultaneous mode when the data width is above 16 bits (conversion data width can exceed 16 bits when functions such as oversampling, compensation and left-bit shift, are used).

  Example:

  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:

  First DMA request: ADCC_CDR2[31:0] = MST_ADC_DR[31:0]

  Second DMA request: ADCC_CDR2[31:0] = SLV_ADC_DR[31:0]

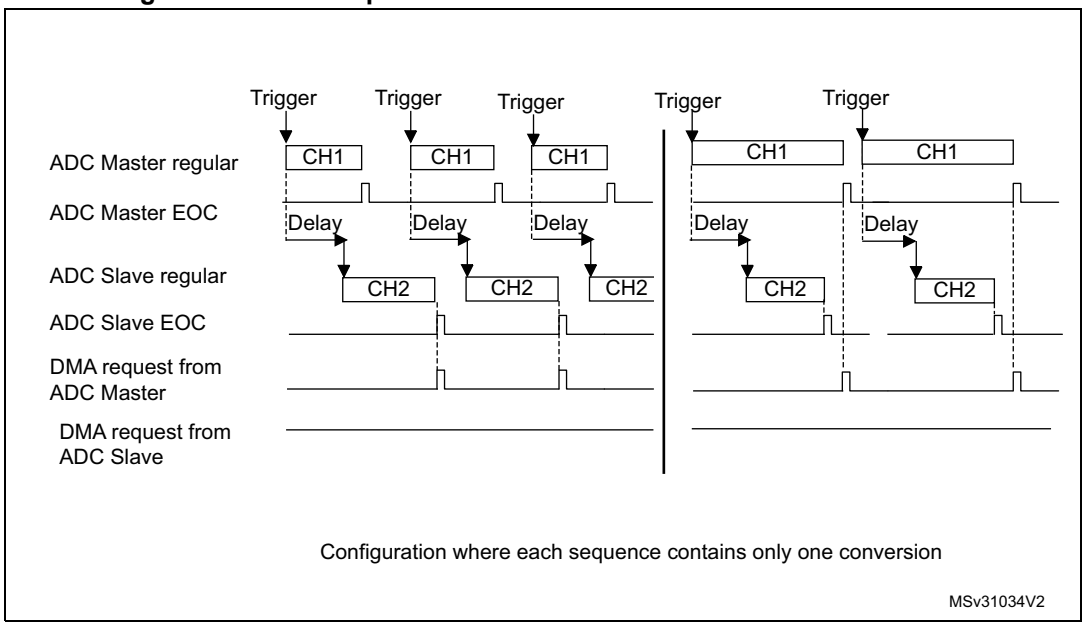
- **DAMDF[1:0] = 0b10, 16-bit format**:

  A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCC_CDR contains the two half-words representing two ADC-converted data. The slave ADC data takes the upper half-word and the master ADC data takes the lower half-word.

  This mode is used in interleaved mode and in regular simultaneous mode when the data width is less than 16 bits. Any value above 16-bit in the master or the slave-converted data is truncated to the least 16 significant bits.

Example:

Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:



First DMA request:

ADCC_CDR[31:0] = (SLV_ADC_DR[15:0] << 16) | MST_ADC_DR[15:0]

Second DMA request:

ADCC_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

Figure 184. DMA requests in interleaved mode when DAMDF = 0b10

Note: When using dual ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion data is available.

- **DAMDF[1:0] = 0b11**:

  This mode is similar to the DAMDF[1:0] = 0b10 configuration. The only difference is that on each DMA request (two data are available), two bytes representing two ADC converted data are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when the resolution is 6 bits or 8 bits and data are not signed

  Example:

  Interleaved dual mode: a DMA request is generated each time two data items are available:

  First DMA request:

  ADCC_CDR[15:0] = (SLV_ADC_DR[7:0] << 8)| MST_ADC_DR[7:0]

  Second DMA request:

  ADCC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

Note: DMA burst mode is not supported in ADC dual mode.

Overrun detection

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). The EOC bit corresponding to one ADC might remains set because the data register of this ADC contains valid data.

DMA one-shot mode/ DMA circular mode when multi-ADC mode is selected

When DAMDF mode is selected (0b10 or 0b11), DMNGT[1:0] bits of the ADCC_CCR register must also be configured to select between DMA one-shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA*

Stopping the conversions in dual ADC modes

In dual ADC mode, the user software must set the ADSTP/JADSTP control bits in the master ADC to stop the conversions of both ADC. The other ADSTP control bit on the slave ADC has no effect in dual ADC mode. Except in DMA one-shot mode, the ADSTP control bit for the master ADC does not affect the slave ADC DMA request signal. In this case, the ADSTP bit must be set on the slave ADC.

Once both ADCs are effectively stopped, the ADSTART/JADSTART bits on the master and slave ADCs are both deasserted by hardware.

Interleaved mode with oversampling

When oversampling is enabled, the ROVSM bit must be set.

Regular sampling in continued mode is supported.

Analog watchdog in dual mode

The analog watchdog is supported in dual mode.

Disabling the ADC in dual mode

During a dual-mode operation, the master ADC shares the ADC clock with the slave ADC. To disable the ADC correctly through the ADDIS bit of ADC_CR, set the ADSTP (or JADSP) bit on the master ADC and, if DUAL[4:0] equals 0b00101, 0b00110, 0b00111, or 0b01001, set ADSTP (or JADSP) on the slave ADC as well. Once ADSTP (or JADSTP) becomes 0 both for the master and slave ADCs, set the ADDIS bit on the slave ADC, then set the ADDIS bit on the master ADC.

ADF mode in dual ADC interleaved mode

In dual ADC interleaved modes (DUAL[4:0] = 0b00011 or DUAL[4:0] = 0b00111), the ADC conversion results can be transferred directly to the ADF.

This mode is enabled by setting DMNGT[1:0] bits to 0b10 in the master ADC ADC_CFGR1 register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the ADF. Each transfer resets the EOC flag of each channel once the transfer is complete.

The data format must be 16-bit signed:

ADC_DR[15:12] = Sign extended

ADC_DR[11] = Sign

ADC_DR[10:0] = Data

To obtain 16-bit signed format, the software must configure OFFSET[11:0] bits to 0x800 with OFFSETy_CH[4:0] selecting the target channel set.

Only right aligned data can be set as ADF input format (see *Figure 149: Right alignment (offset enabled, signed value)*).

ADF mode in dual ADC simultaneous mode

It is not mandatory to use the ADF in dual ADC simultaneous mode since conversion data are handled by each individual channel. Single mode with same trigger source results in simultaneous conversion with ADF interface.

Dual ADC modes supported in oversampling mode

It is possible to have oversampling enabled when working in dual ADC configuration for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

22.4.32 Temperature sensor

The temperature sensor can be used to measure the junction temperature (T_J) of the device.

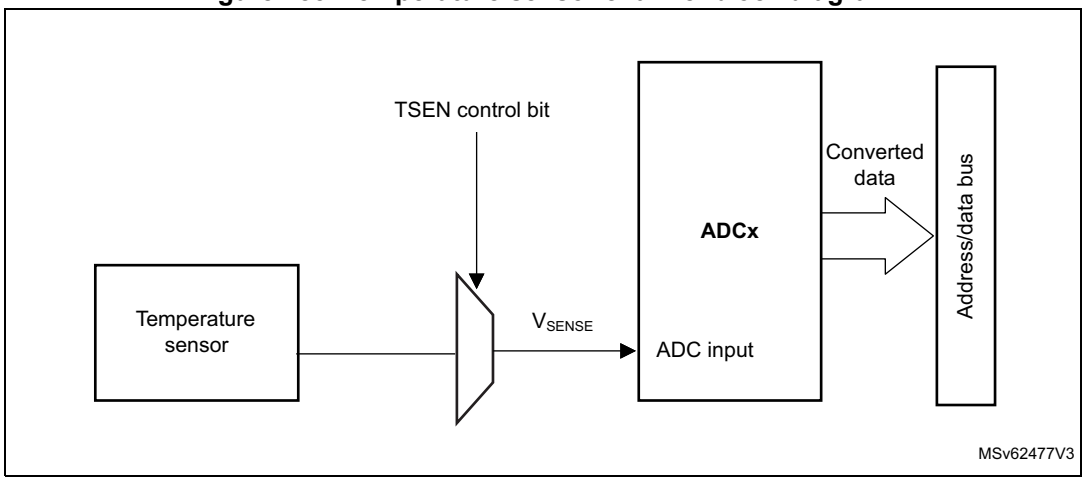
The temperature sensor is internally connected to the ADC input channels, which are used to convert the sensor output voltage to a digital value (see *Table: ADC interconnection* in *Section 22.4.2: ADC pins and internal signals* for more details). When not in use, the sensor

can be put in power-down mode. It supports the temperature range specified in the product datasheet.

Figure 185 shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.



During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel, which is used to convert the sensor's output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

Figure 185 shows the block diagram of the temperature sensor.

Figure 185. Temperature sensor channel block diagram

Reading the temperature

To use the sensor:

1. Select the ADC input channel that is connected to V_{SENSE}.
2. Program with the appropriate sampling time (refer to the electrical characteristics section of the device datasheet).
3. Set the TSEN bit in the ADCC_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting V_{SENSE} data in the ADC data register.

6. Calculate the actual temperature using the following formula:

$$\text{Temperature (in °C)} = \frac{\text{TS_CAL2_TEMP} - \text{TS_CAL1_TEMP}}{\text{TS_CAL2} - \text{TS_CAL1}} \times (\text{TS_DATA} - \text{TS_CAL1}) + \text{TS_CAL1_TEMP}$$

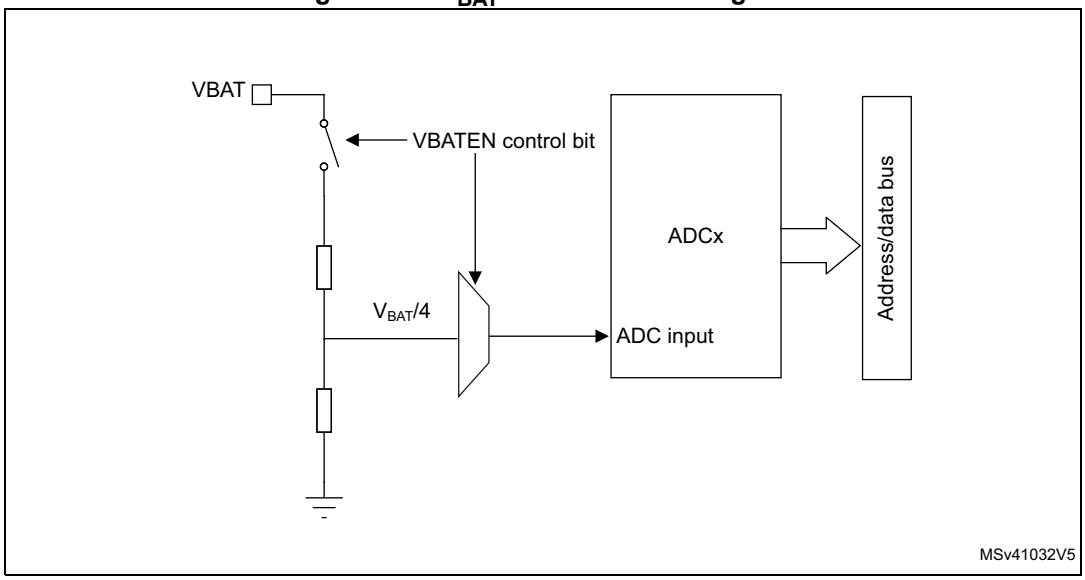
Where:

- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

  Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Caution: The above formula is valid only if the V_{REF+} condition specified in the table *Temperature sensor calibration values* of the datasheet are respected.

Note: The sensor has a startup time after waking from power-down mode before it can output V_{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN, and TSEN bits should be set simultaneously.



22.4.33 V_{BAT} supply monitoring

The VBATEN bit in the ADCC_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage can be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}/4$ to the ADC input channels (see *Table: ADC interconnection* in *Section 22.4.2: ADC pins and internal signals* for more details). As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

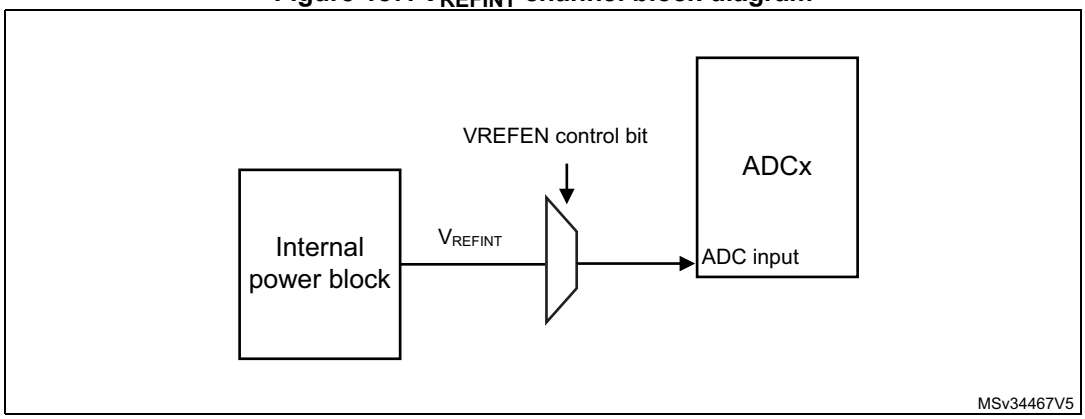
Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/4$ voltage.

Figure 186 shows the block diagram of the V_{BAT} sensing feature.

Figure 186. V_{BAT} channel block diagram

1. The VBATEN bit must be set to enable the conversion of internal channel for $V_{BAT}/4$.

22.4.34 Monitoring the internal voltage reference



It is possible to monitor the internal voltage reference (V_{REFINT}) to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to the *ADC interconnection* table in *Section 22.4.2: ADC pins and internal signals* for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

Figure 187 shows the block diagram of the V_{REFINT} sensing feature.

Figure 187. V_{REFINT} channel block diagram

1. The VREFEN bit of the ADCC_CCR register must be set to enable the conversion of internal channels (V_{REFINT}).

Calculating the actual V_{REF+} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = V_{REF+_Charac} \times VREFINT_CAL / VREFINT_DATA$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process. It is specified in the device datasheet.
- VREFINT_CAL is the VREFINT calibration value.
- VREFINT_DATA is the actual VREFINT output value converted by ADC.

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For some applications, the V_{REF+} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{REF+}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

For applications where V_{REF+} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value.
- ADC_DATA is the value measured by the ADC on channel x (right-aligned).
- VREFINT_DATA is the actual VREFINT output value converted by the ADC.
- FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, we obtain $2^{12} - 1 = 4095$, or $2^8 - 1 = 255$ with 8-bit resolution.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

22.4.35 Monitoring the DAC output voltage

The ADC is connected to a DAC internal channel. To measure the DAC output voltage, enable the DAC internal channel through DAC registers.

22.4.36 Monitoring the supply voltage

The ADCs are connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.

22.5 ADC in low-power modes

Table 190. Effect of low-power modes on the ADC

Mode	Description
Sleep	No effect. DMA requests are functional. ADC interrupts cause the device to exit from Sleep mode.
Stop 0/1/2/3	The ADC is no more functional. The ADC must be powered down before entering Stop mode. The content of the ADC registers is kept.
Standby/Shutdown	The ADC is powered down and must be reinitialized after exiting Standby or Shutdown mode.

22.6 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (ADRDY flag)
- On the end of any conversion for regular groups (EOC flag)
- On the end of a sequence of conversion for regular groups (EOS flag)
- On the end of any conversion for injected groups (JEOC flag)
- On the end of a sequence of conversion for injected groups (JEOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2 and AWD3 flags)
- When the end of the sampling phase occurs (EOSMP flag)
- When the data overrun occurs (OVR flag)
- When the ADC internal voltage regulator output is ready (LDORDY flag)
- When the injected sequence context queue overflows (JQOVF flag)

Separate interrupt enable bits are available for flexibility.

Note: Interrupts are generated by the AHB clock domain. Since the ADC clock is adc_ker_ck, interrupt flags are delayed due to the synchronization between adc_ker_ck and AHB clock domains.

Table 191. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby mode
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No
	End of conversion of a regular group	EOC	EOCIE			
	End of conversion sequence of a regular group	EOS	EOSIE			
	End of conversion of an injected group	JEOC	JEOCIE			
	End of conversion sequence of an injected group	JEOS	JEOSIE			
	Analog watchdog 1 flag is set	AWD1	AWD1IE			
	Analog watchdog 2 flag is set	AWD2	AWD2IE			
	Analog watchdog 3 flag is set	AWD3	AWD3IE			
	End of sampling phase	EOSMP	EOSMPIE			
	Overrun	OVR	OVRIE			
	ADC internal voltage regulator ready	LDORDY	LDORDYIE			
	Injected context queue overflows	JQOVF	JQOVFIE			

22.7 ADC registers (for each ADC)

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

22.7.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDY	Res.	JQOVF	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
			rc_w1		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY**: ADC internal voltage regulator output ready flag

This bit is set by hardware and cleared by software. It indicates that the ADC internal voltage regulator output is ready and that the ADC can be enabled or calibrated.

0: ADC LDO internal voltage regulator disabled

1: ADC LDO internal voltage regulator enabled

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVF**: Injected context queue overflow

This bit is set by hardware when an overflow of the injected queue of context occurs. It is cleared by software writing 1 to it. Refer to *Section 22.4.21: Queue of context for injected conversions* for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)

1: Injected context queue overflow has occurred

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD3LTR and ADC_AWD3HTR registers. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD2LTR and ADC_AWD2HTR registers. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD1LTR and ADC_AWD1HTR registers. It is cleared by software. writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it, or by reading the corresponding ADC_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel (a new conversion has completed while the EOC flag was already set) or when adc_hclk clock is too slow to manage the data.

It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Note: When the OVR flag is raised, the EOSMP flag is not generated correctly.

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

22.7.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDYIE	Res.	JQOVFIE	AWD3IE	AWD2IE	AWD1IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDYIE**: ADC internal voltage regulator interrupt enable

This bit is set and cleared by software to enable/disable the ADC internal voltage regulator interrupt.

0: Internal voltage regulator interrupt disabled

1: Internal voltage regulator interrupt enabled

Note: The software is allowed to write this bit only when ADEN = 0.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVFIE**: Injected context queue overflow interrupt enable

This bit is set and cleared by software to enable/disable the injected context queue overflow interrupt.

0: Injected context queue overflow interrupt disabled

1: Injected context queue overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

22.7.3 ADC control register (ADC_CR)

Address offset: 0x008

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	Res.	DEEPPWD	ADVREGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs		rw	rw												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to enter ADC calibration mode.

0: Normal mode

1: Calibration mode

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing)

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

0: ADC not in Deep-power down

1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0 and ADEN =0).

Bit 28 **ADVREGEN**: ADC internal voltage regulator enable

This bits is set by software to enable the ADC internal voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC internal voltage regulator disabled

1: ADC internal voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to *Section 22.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*.

The software can program this bit field only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be reconfigured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

When a software trigger is used, JADSTART bit is cleared by hardware, but JADSTP bit must be programmed to reconfigure the ADC.

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP command).

It is cleared by hardware when the conversion is effectively discarded. and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

When a software trigger is used, ADSTART bit is cleared by hardware. However it is necessary to write ADSTP bit to reconfigure the ADC.

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop ongoing regular conversions. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use ADSTP).

Note: In dual ADC regular simultaneous mode and interleaved mode, the ADSTP bit of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

This bit is cleared by hardware:

– In single conversion mode when software trigger is selected (JEXTSEL=0x0 and JDISEN = 1): at the assertion of the end of injected conversion sequence (JEOS) flag.

– In all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1,ADDIS = 0 and JAUTO = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared).

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

This bit is cleared by hardware:

– in single conversion mode when software trigger is selected (EXTSEL = 0x0 and DISEN = 1): at the assertion of the end of regular conversion sequence (EOS) flag.

– in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and place it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1, ADDIS = 0 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all the bits of ADC_CR registers are cleared (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0), except for ADVREGEN bit which must be set. In addition, the software must wait for the startup time of the voltage regulator.

22.7.4 ADC configuration register (ADC_CFGR1)

Address offset: 0x00C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JQDIS	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	JQM	JDISCEN	DISCNUM[2:0]			DISCEN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					Res.	RES[1:0]		DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bit 31 **JQDIS**: Injected queue disable

This bit is set and cleared by software to disable the injected queue mechanism:

0: Injected queue enabled

1: Injected queue disabled

Note: The software is allowed to write this bit only when ADEN = 0, ADSTART = 0, and JADSTART = 0.

Note: A set or reset of JQDIS bit causes the injected queue to be flushed and the ADC_JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel 0 monitored by AWD1

00001: ADC analog input channel 1 monitored by AWD1

.....

10010: ADC analog input channel 18 monitored by AWD1

Others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.

Note: The channel selected by AWD1CH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADEN = 0, ADSTART = 0, and JADSTART = 0.

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the JAUTO bit of the master ADC.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 **JQM**: ADC_JSQR queue mode

This bit is set and cleared by software.

It defines how an empty Queue is managed.

0: ADC_JSQR mode 0: The Queue is never empty and maintains the last written configuration to ADC_JSQR.

1: ADC_JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to *Section 22.4.21: Queue of context for injected conversions* for more information.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: When dual mode is enabled (DUAL bits of ADCC_CCR register are not equal to zero), the JDISCEN bit of the slave ADC is no more writable and its content is equal to the JDISCEN bit of the master ADC.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCNUM[2:0] bits of the slave ADC are no more writable and their content is equal to the DISCNUM[2:0] bits of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bits of the slave ADC is no more writable and its content is equal to the DISCEN bit of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the autodelayed conversion mode.

0: Autodelayed conversion mode off

1: Autodelayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bits of the slave ADC is no more writable and its content is equal to the DISCEN bit of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bits of the slave ADC is no more writable and its content is equal to the DISCEN bit of the master ADC.

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0

00001: adc_ext_trg1

00010: adc_ext_trg2

00011: adc_ext_trg3

00100: adc_ext_trg4

00101: adc_ext_trg5

00110: adc_ext_trg6

00111: adc_ext_trg7

...

11111: adc_ext_trg31

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit

01: 10-bit

10: 8-bit

11: 6-bit

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data management configuration

These bits are set and cleared by software to select how the ADC interface output data are managed.

00: Regular conversion data stored in DR only

01: DMA one-shot mode selected

10: ADF mode selected

11: DMA circular mode selected

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

22.7.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSHIFT[3:0]				Res.	Res.	OVSR[9:0]									
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPTRIG	SWTRIG	BULB	Res.	Res.	ROVSM	TROVS	OVSS[3:0]				Res.	Res.	Res.	JOVSE	ROVSE
rw	rw	rw			rw	rw	rw	rw	rw	rw				rw	rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OVSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

0: Sampling time control trigger mode disabled

1: Sampling time control trigger mode enabled

If EXTEN[1:0] bits are set to 01, the sampling time starts on the trigger rising edge, and the conversion starts on the trigger falling edge.

The SMPTRIG bit must not be set when the SMPTRIG bit is set.

When EXTEN[1:0] bits are set to 00, set SWTRIG to start the sampling and clear the BULB bit to start the conversion.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with sampling time control trigger mode*.*

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to trigger the conversion in sampling time control trigger mode.

0: Software trigger starts the conversion for sampling time control trigger mode

1: Software trigger starts the sampling for *sampling time control trigger mode*

Note: The software is allowed to write this bit only when ADSTART = 0, JADSTART = 0 (which ensures that no conversion is ongoing), SMPTRIG = 1, and EXTEN[0:1] = 00.

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

BULB bit must not be set when the SWTRIG bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with bulb mode.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). It is recommended to clear both JOVSE and GCOMP when ROVSM = 0.

Bit 9 **TROVS**: Triggered regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift
0001: 1-bit shift
0010: 2-bit shift
0011: 3-bit shift
0100: 4-bit shift
0101: 5-bit shift
0110: 6-bit shift
0111: 7-bit shift
1000: 8-bit shift
1001: 9-bit shift
1010: 10-bit shift
Other: reserved, must not be used

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected oversampling enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected oversampling disabled
1: Injected oversampling enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ROVSE**: Regular oversampling enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular oversampling disabled
1: Regular oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing)

22.7.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP5[0]	SMP4[2:0]			SMP3[2:0]			SMP2[2:0]			SMP1[2:0]			SMP0[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 6.5 ADC clock cycles
011: 11.5 ADC clock cycles
100: 23.5 ADC clock cycles
101: 46.5 ADC clock cycles
110: 246.5 ADC clock cycles
111: 1499.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

22.7.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	SMP18[2:0]			SMP17[2:0]			SMP16[2:0]			SMP15[2:1]	
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP15[0]	SMP14[2:0]			SMP13[2:0]			SMP12[2:0]			SMP11[2:0]			SMP10[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:0 **SMPx[2:0]:** Channel x sampling time selection (x = 18 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 6.5 ADC clock cycles
011: 11.5 ADC clock cycles
100: 23.5 ADC clock cycles
101: 46.5 ADC clock cycles
110: 246.5 ADC clock cycles
111: 1499.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

22.7.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x01C

Reset value: 0x0000 0000

PCSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 **PCSEL[18:0]**: Channel i ($V_{IN[i]}$) preselection

These bits are written by software to preselect the input channel I/O to be converted.

0: Input channel i ($V_{IN[i]}$) is not preselected for conversion, the result of the ADC conversion for this channel is wrong

1: Input channel i ($V_{IN[i]}$) is preselected for conversion

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

22.7.9 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SQ2[3:0]				Res.	SQ1[4:0]					Res.	Res.	L[3:0]			
rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 1st in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular channel conversion sequence.
0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

22.7.10 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 9th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 8th in the regular conversion sequence
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 7th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

22.7.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0 to 18) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 12th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 11th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 10th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

22.7.12 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 16th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 15th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

22.7.13 ADC regular data register (ADC_DR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 22.4.26: Data management*.

22.7.14 ADC injected sequence register (ADC_JSQR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

...

11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

22.7.15 ADC offset y configuration register (ADC_OFCFGRy)

Address offset: 0x050 + 0x004 * (y -1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_CH[4:0]					SSAT	USAT	POS OFF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:27 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed in bits OFFSET[21:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the data offset y.

Bit 26 **SSAT**: Signed saturation enable

This bit is set and cleared by software to enable the signed saturation feature.(see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*).

0: Offset is subtracted maintaining the data integrity and extending converted data size (13-bit signed format)

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **USAT**: Unsigned saturation enable

This bit is set and cleared by software to enable the unsigned saturation feature.

0: Offset is subtracted maintaining the data integrity

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: Positive offset enable

This bit is set and cleared by software to enable the positive offset

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 Reserved, must be kept at reset value.

22.7.16 ADC offset y register (ADC_OFRy)

Address offset: 0x060 + 0x004 * (y -1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OFFSET[21:16]

OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **OFFSET[21:0]:** Data offset y for the channel programmed in OFFSETy_CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the OFFSETy_CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

22.7.17 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x070

Reset value: 0x0000 1000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
G COMP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	GCOMPCOEFF[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GCOMP:** Gain compensation mode

This bit is set and cleared by software to enable the Gain compensation mode.

0: Regular ADC operation mode

1: Gain compensation enabled and applied on all channels.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing)

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 **GCOMPCOEFF[13:0]:** Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.

00 1000 0000 0000: gain factor of 0.5

...

01 0000 0000 0000: gain factor of 1

10 0000 0000 0000: gain factor of 2

11 0000 0000 0000: gain factor of 3

...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.9999756

Note: This gain compensation is only applied when GCOMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing).

22.7.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x080 + 0x004 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWDCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 **AWDCH[18:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD2

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWDCH[18:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWDCH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

22.7.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

AWDCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 **AWDCH[18:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD3

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWDCH[18:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWDCH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

22.7.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter
These bits are set and cleared by software.
000: No filtering, one detection generates an AWD1 flag or an interrupt
001: two consecutive detections generate an AWD1 flag or an interrupt
...
111: Eight consecutive detections generate an AWD1 flag or an interrupt
Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 1 higher threshold
These bits are set and cleared by software to define the higher threshold for analog watchdog 1. Refer to *Analog windows watchdog* section.

22.7.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR)

Address offset: 0x0B0

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT[6:0]**: Calibration factors

These bits can be written by hardware or by software.

Once the calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is applied once a new conversion is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled, no conversion is ongoing).

22.7.28 ADC option register (ADC_OR)

Address offset: 0x0D0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP0
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **OP0:** Option bit 0

This bit is set and cleared by software to enable the V_{CORE} channel.

0: V_{CORE} disabled

1: V_{CORE} enabled

22.8 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

22.8.1 ADC common status register (ADCC_CSR)

Address offset: 0x000

Reset value: 0x0000 0000

This register provides an image of the flags of the different ADCs. Nevertheless it is read-only and does not allow to clear the different flags. Instead each flag must be cleared by writing 0 to it in the corresponding ADC_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			r		r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **LDORDY_SLV:** ADC internal voltage regulator flag of the slave ADC

This bit is a copy of the LDORDY bit in the corresponding ADC_ISR register.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **JQOVF_SLV:** Injected context queue overflow flag of the slave ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17 **EOSMP_SLV:** End of sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY_MST:** ADC internal voltage regulator flag of the master ADC
This bit is a copy of the LDORDY bit in the corresponding ADC_ISR register.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVF_MST:** Injected context queue overflow flag of the master ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

22.8.2 ADC common control register (ADCC_CCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	TSEN	VREFEN	Res.	Res.	Res.	Res.	Res.	Res.
							rw	rw	rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAMDF[1:0]		Res.	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable
This bit is set and cleared by software to enable/disable the V_{BAT} channel.
0: V_{BAT} channel disabled
1: V_{BAT} channel enabled
Note: V_{BAT} is not available on all ADC instances. Refer to Section 22.4.4: ADC connectivity for details.

Bit 23 **TSEN**: Temperature sensor voltage enable
This bit is set and cleared by software to control V_{SENSE} channel.
0: Temperature sensor channel disabled
1: Temperature sensor channel enabled
Note: The temperature sensor is not available on all ADC instances. Refer to Section 22.4.4: ADC connectivity for details.
Note: The software is allowed to write this bit only when ADEN = 0.

Bit 22 **VREFEN**: V_{REFINT} enable
This bit is set and cleared by software to enable/disable the V_{REFINT} channel.
0: V_{REFINT} channel disabled
1: V_{REFINT} channel enabled
Note: V_{REFINT} is not available on all ADC instances. Refer to Section 22.4.4: ADC connectivity for details.
Note: The software is allowed to write this bit only when ADEN = 0.

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:14 **DAMDF[1:0]:** Dual ADC mode data format

This bitfield are set and cleared by software. It specifies the data format in the common data register ADCC_CDR and ADCC_CDR2.
00: Dual ADC mode without data packing (ADCC_CDR and ADCC_CDR2 registers not used).
01: Reserved
10: Data formatting mode for any data width (ADCC_CDR data register is used when the data width is less than 16 bits, otherwise ADCC_CDR2 register is used)
11: Data formatting mode for data width lower that 8 bits (ADCC_CDR data register is used)

Note: The software is allowed to write these bits only when ADEN = 0 (which ensures that no regular conversion is ongoing).

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between two sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to *Table 189* for the value of ADC resolution versus DELAY bits values.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection

These bits are written by software to select the operating mode.
All the ADCs independent:
00000: Independent mode
The following settings apply to dual mode, master and slave ADCs working together
00001: Combined regular simultaneous + Injected simultaneous mode
00010: Combined regular simultaneous + Alternate trigger mode
00011: Combined interleaved mode + Injected simultaneous mode
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
Others: Reserved
All other combinations are reserved and must not be programmed

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

22.8.3 ADC common regular data register for dual mode (ADCC_CDR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]

RDATA_MST[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA_SLV[15:0]:** Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to *Section 22.4.31: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to *Section 22.4.31: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*)

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

22.8.4 ADC common regular data register for dual mode (ADCC_CDR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDATA_ALT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs.

In dual mode, these bits contain the regular 32-bit data of the master and the slave ADC. Refer to *Section 22.4.31: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*)

22.9 ADC register map

ADC1 and ADC2 are master and slave ADC, respectively.

Table 192. ADC register map and reset values for each ADC

Refer to *Section 2.3* for the register boundary addresses.

23 Digital-to-analog converter (DAC)

23.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, VREF+ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to *voltage reference buffer (VREFBUF)* section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the sample and hold mode.

23.2 DAC main features

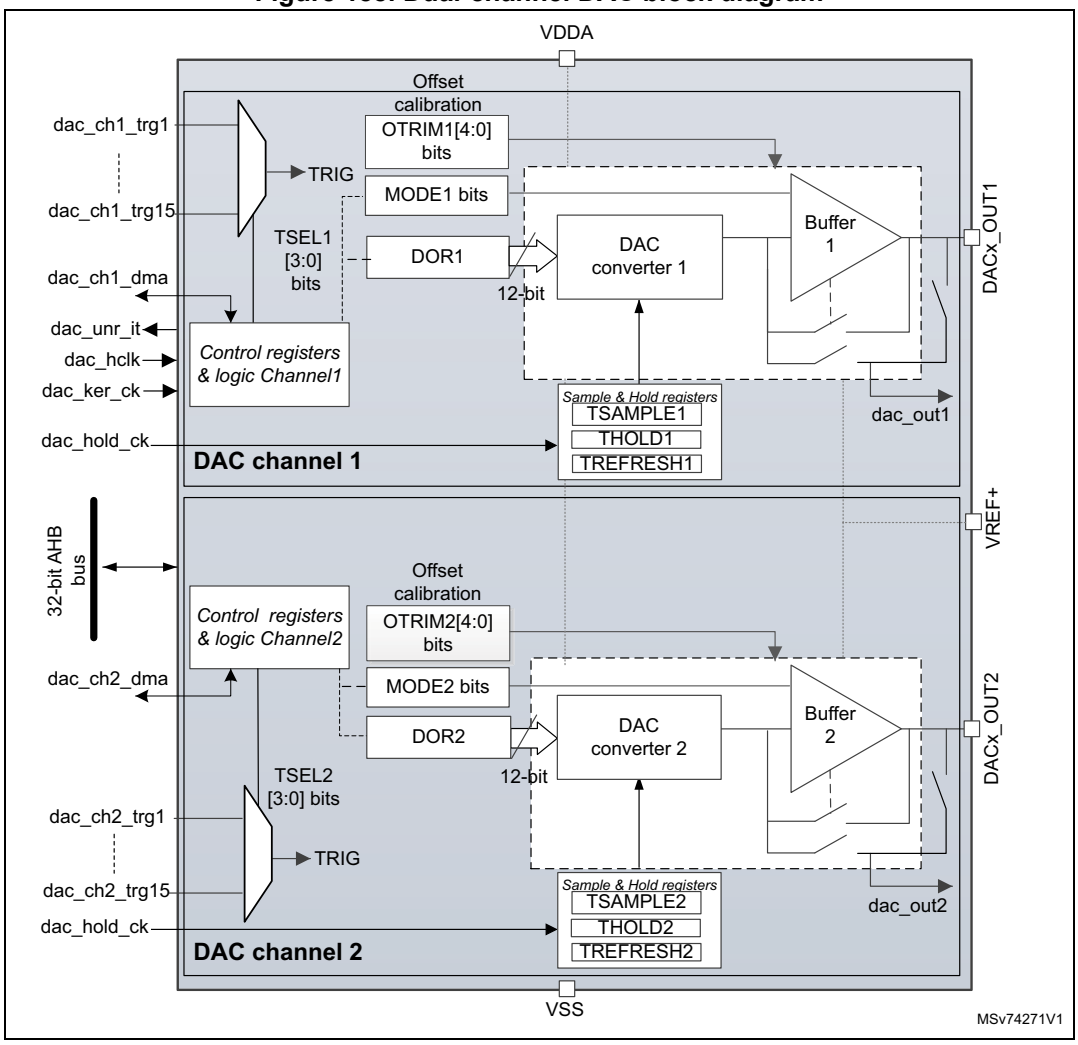
The DAC main features are the following (see *Figure 188: Dual-channel DAC block diagram*)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Autonomous mode to reduce the power consumption for the system
- Input voltage reference from VREF+ pin or internal VREFBUF reference

Figure 188 shows the block diagram of a DAC channel and *Table 195* gives the pin description.

23.3 DAC implementation

Table 194. DAC features



DAC features	DAC1
Dual channel	X
Output buffer	X
I/O connection	DAC1_OUT1 on PA4, DAC1_OUT2 on PA5
Maximum sampling time	1 Msps
Autonomous mode(1)	X

1. The autonomous mode is supported in Stop 1 mode.

23.4 DAC functional description

23.4.1 DAC block diagram

Figure 188. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and allow switching between the normal mode in buffer/unbuffered configuration and the sample and hold mode.
2. Refer to *Section 23.3: DAC implementation* for channel2 availability.

23.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

Table 195. DAC input/output pins

Pin name	Signal type	Remarks
VREF+	Input, analog positive reference	The higher/positive reference voltage for the DAC, $V_{REF+} \leq V_{DDAmax}$ (refer to datasheet)
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply
DACx_OUTy	Analog output signal	DACx channely analog output

Table 196. DAC internal input/output signals

Internal signal name	Signal type	Description
dac_ch1_dma	Bidirectional	DAC channel1 DMA request/acknowledge
dac_ch2_dma	Bidirectional	DAC channel2 DMA request/acknowledge
dac_ch1_trgx (x = 1 to 15)	Inputs	DAC channel1 trigger inputs
dac_ch2_trgx (x = 1 to 15)	Inputs	DAC channel2 trigger inputs
dac_unr_it	Output	DAC underrun interrupt
dac_hclk	Input	DAC peripheral clock
dac_ker_ck	Input	DAC kernel clock
dac_hold_ck	Input	DAC low-power clock used in sample and hold mode
dac_out1	Analog output	DAC channel1 output for on-chip peripherals
dac_out2	Analog output	DAC channel2 output for on-chip peripherals

Table 197. DAC interconnection

Signal name	Source	Source type
dac_hold_ck	ck_lsi or ck_lse	LSI or LSE clock selected in the RCC
dac_chx_trg1 (x = 1, 2)	tim1_trgo	Internal signal from on-chip timers
dac_chx_trg2 (x = 1, 2)	tim2_trgo	Internal signal from on-chip timers
dac_chx_trg3 (x = 1, 2)	tim4_trgo	Internal signal from on-chip timers
dac_chx_trg4 (x = 1, 2)	Reserved	Internal signal from on-chip timers
dac_chx_trg5 (x = 1, 2)	tim6_trgo	Internal signal from on-chip timers
dac_chx_trg6 (x = 1, 2)	tim7_trgo	Internal signal from on-chip timers
dac_chx_trg7 (x = 1, 2)	Reserved	Internal signal from on-chip timers
dac_chx_trg8 (x = 1, 2)	tim15_trgo	Internal signal from on-chip timers
dac_chx_trg11 (x = 1, 2)	lptim1_ch1	Internal signal from on-chip timers
dac_chx_trg12 (x = 1, 2)	lptim3_ch1	Internal signal from on-chip timers
dac_chx_trg13 (x = 1, 2)	exti9	External pin

23.4.3 DAC clocks

Two clock sources can be used to update the DAC:

- dac_hclk: DAC peripheral clock (AHB clock)
- dac_ker_ck: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- dac_hold_ck: low-power clock used in sample and hold mode

The DAC clock is selected in the RCC.

23.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a t_{WAKEUP} startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

23.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:

  – 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)

  – 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)

  – 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DAC_DHRx (data holding registerx, which are internal non-memory-mapped registers). The DAC_DHRx register is then loaded into the DAC_DORx register either automatically, by software trigger or by an external event trigger.

Figure 189. Data registers in single DAC channel mode

- Dual DAC channels (when available)

  There are three possibilities:

  – 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

  – 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

  – 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 190. Data registers in dual DAC channel mode

Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2's complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB of the data written to DAC_DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB is inverted. The four LSBs are simply ignored.

Table 198. Data format (case of 12-bit data)

SINFORMATx bit	DATA written to DAC_DHRx register	DATA transfered to DAC_DORx register
0	0x000	0x000
0	0xFFF	0xFFF
1	0x7FF	0xFFF
1	0x000	0x800
1	0xFFF	0x7FF
1	0x800	0x000

23.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

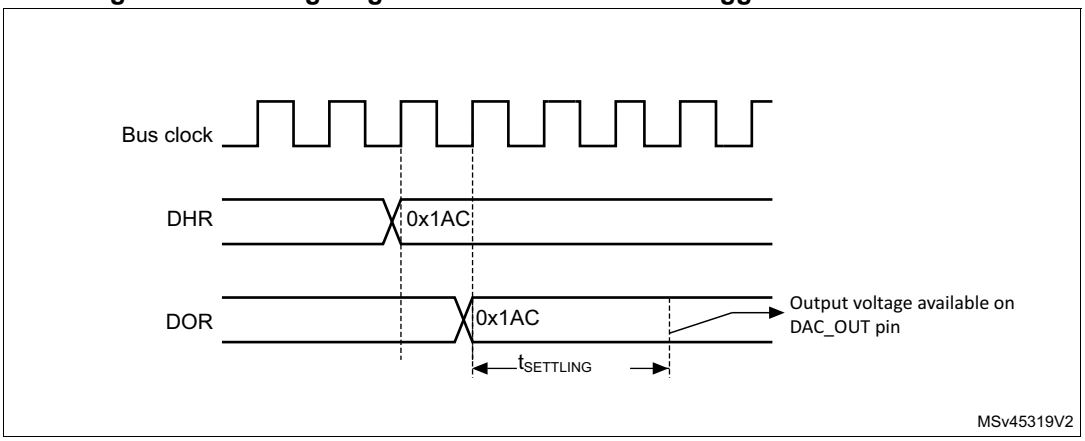
When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{SETTLING}$ that depends on the power supply voltage and the analog output load.

To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_ker_ck clock speed is faster than 80 MHz.

Refer to Table *HFSEL description* below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk or dac_ker_ck clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.



The above timing is only related to the limitation of the DAC interface. Refer also to the $t_{SETTLING}$ parameter value in the product datasheet.

Table 199. HFSEL description

HFSEL [1:0]	Clock frequency	Latency using AHB clock (dac_hclk)	Latency using dac_ker_ck clock	Function
00	< 48 MHz	3	4	DAC_DOR update rate up to 3 AHB clock cycles or 4 dac_ker_ck cycles.
01	≥ 48 MHz(1)	5	5	DAC_DOR update rate up to 5 AHB clock or dac_ker_ck cycles.
11	Reserved	-	-	-

1. Refer to the device datasheet for the value of the maximum dac_hclk or dac_ker_ck frequency.

Figure 191. Timing diagram for conversion with trigger disabled TEN = 0

23.4.7 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and V_{REF+}.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DAC output} = V_{REF} \times \frac{DOR}{4096}$$

where all voltages are expressed in Volt.

23.4.8 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

23.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

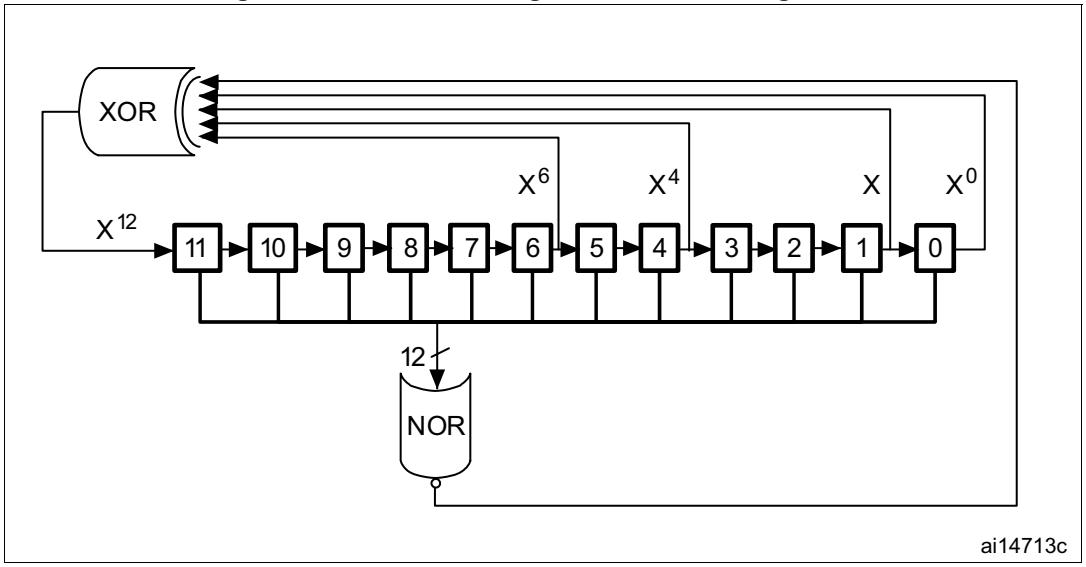
DMA double data mode

When the DMA controller is used in normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.
2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA double data mode.



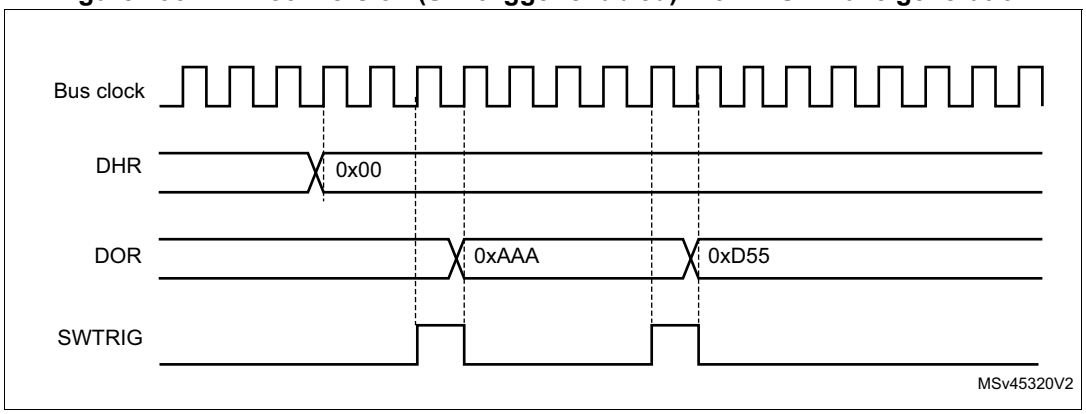
The following conditions must be met to change from double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

23.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.

Figure 192. DAC LFSR register calculation algorithm



The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a 1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 193. DAC conversion (SW trigger enabled) with LFSR wave generation

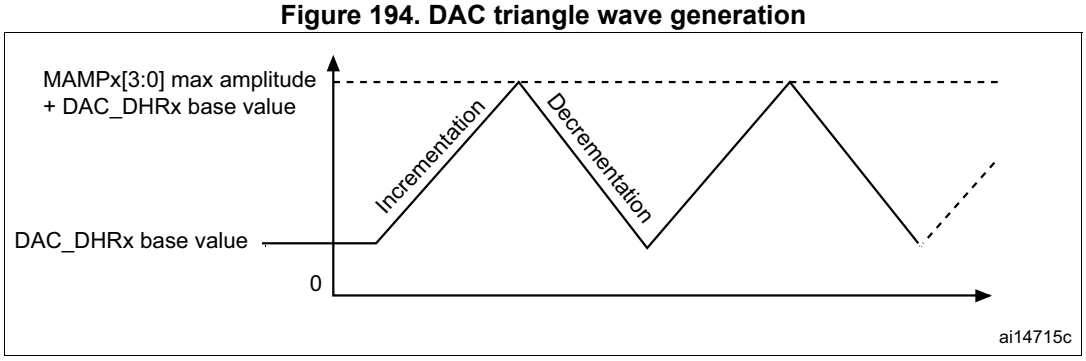
Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

23.4.11 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 194. DAC triangle wave generation



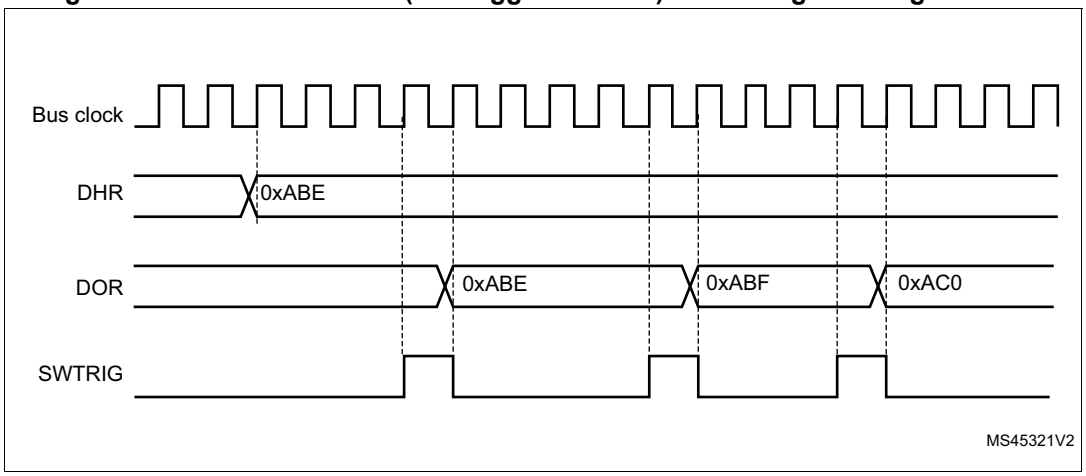


Figure 195. DAC conversion (SW trigger enabled) with triangle wave generation

Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.

23.4.12 DAC channel modes

Each DAC channel can be configured in normal mode or sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the sample and hold mode is enabled.

The sample/hold mode operations can be divided into three phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register
3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11.
- 62 cycles are required for hold phase: THOLDx[9:0] = 62.
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 200. Sample and refresh timings

Buffer State	t_{SAMP} (1)(2)	$t_{REFRESH}$ (2)(3)
Enable	7 µs + (10*R_{BON}*C_{SH})	7 µs + (R_{BON}*C_{SH})*ln(2*N_{LSB})
Disable	3 µs + (10*R_{BOFF}*C_{SH})	3 µs + (R_{BOFF}*C_{SH})*ln(2*N_{LSB})

1. In the above formula, the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8-bit resolution, the settling time is 7 constant time.
2. C_{SH} is the capacitor in sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*Nlsb) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

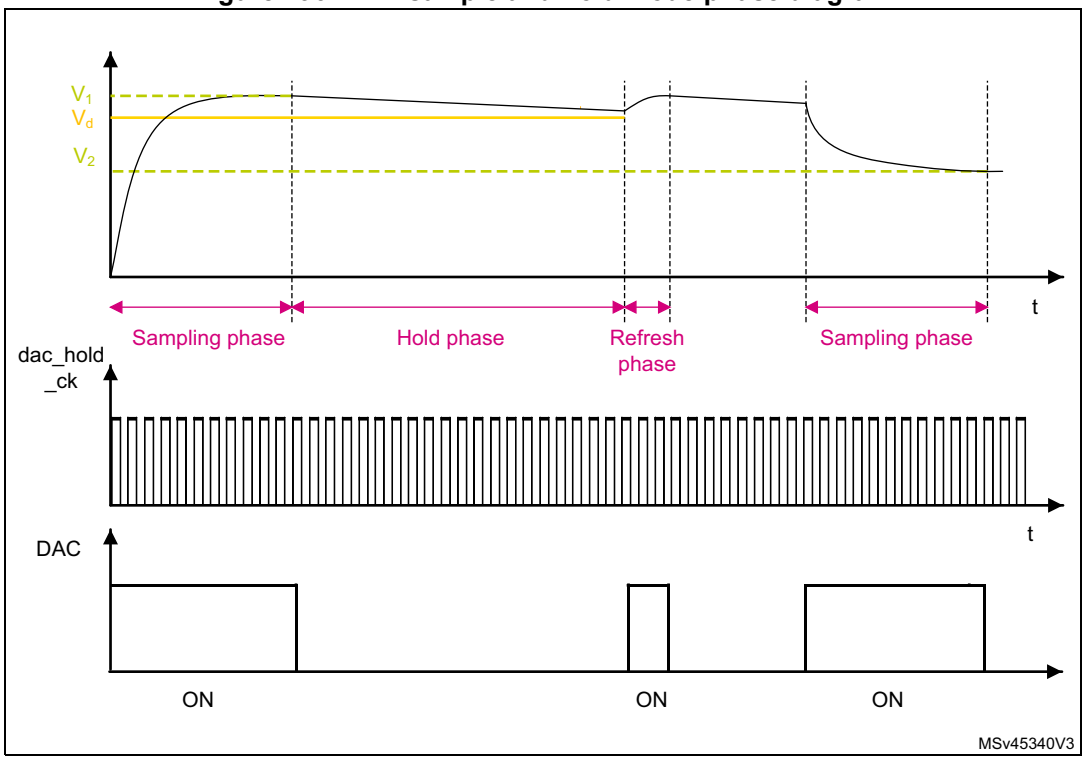
The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

C_{SH} = 100 nF

V_{REF+} = 3.0 V

Sampling phase:

t_{SAMP} = 7 µs + (10 * 2000 * 100 * 10^{-9}) = 2.007 ms
(where R_{BON} = 2 kΩ)



Refresh phase:

$t_{REFRESH}$ = 7 µs + (2000 * 100 * 10^{-9}) * ln(2*10) = 606.1 µs
(where N_{LSB} = 10 (10 LSB drop during the hold phase)

Hold phase:

$D_v = i_{leak} * t_{hold} / C_{SH}$ = 0.0073 V (10 LSB of 12bit at 3 V)
i_{leak} = 150 nA (worst case on the IO leakage on all the temperature range)
t_{hold} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 ms

Figure 196. DAC sample and hold mode phase diagram

Like in normal mode, the sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

  When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{Lint}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

Table 201. Channel output modes summary

MODEx[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	0	1			Connected to external pin and to on chip-peripherals (such as comparators)
0	1	0		Disabled	Connected to external pin
0	1	1			Connected to on chip peripherals (such as comparators)
1	0	0	Sample and hold mode	Enabled	Connected to external pin
1	0	1			Connected to external pin and to on chip peripherals (such as comparators)
1	1	0		Disabled	Connected to external pin and to on chip peripherals (such as comparators)
1	1	1			Connected to on chip peripherals (such as comparators)

23.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = \left((D / 2^N) \times G \times V_{REF}\right) + V_{OS}$$

Where V_{OUT} is the analog output, D is the digital input, G is the gain, V_{REF} is the nominal full-scale voltage, and V_{OS} is the offset voltage. For an ideal DAC channel, G = 1 and V_{OS} = 0.

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the V_{OS}, a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to V_{REF+}/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)

  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming

  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when V_{DDA} voltage, temperature, V_{REF+} values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the nominal factory trimming conditions.

In addition, when V_{DD} is removed (example the device enters in Standby mode) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for t_{TRIM} delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) Until the CAL_FLAGx is read as 1 or the maximum trimming code is reached, increment OTRIMx[4:0] and repeat substeps from (b) to (d).

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

Note: A t_{TRIM} delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value.This parameter is specified into datasheet electrical characteristics section.

If V_{DDA}, V_{REF+} and temperature conditions do not change during device operation while it enters more often in Standby mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

23.4.14 DAC channel conversion modes

Four conversion modes are possible.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Load the DAC channel data into the desired DHR registers (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DHRx register is transferred into DAC_DORx (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bits, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DAC channel triangle counter, with the same triangle amplitude, is added to the DHRx register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel triangle counter is then updated.

Independent trigger with single sawtooth generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Configure the trigger sources by setting different values in STRSTTRIGSELx[3:0] and STINCTRIGSELx[3:0] bits.
2. Configure the DAC channel WAVEx[1:0] bits to 11 and set the same STRSTDATAx[11:0], STINCDATAx[15:0] and STDIRx values for each register.

When a DAC channel trigger arrives, the DAC channel sawtooth counter updates the DHRx register and transfers it into DAC_DOR1 (three AHB clock cycles later).

23.4.15 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DAC_DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

Simultaneous trigger with single LFSR generation

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated.
At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

23.4.16 DAC autonomous mode

The autonomous mode can be used to update the DAC output voltage in Stop mode. This allows DMA transfers to be performed when the device operates in Run, Sleep or Stop mode. The autonomous mode is supported AUTOMODE only when the DAC is in sample and hold mode. It is enabled by setting the bit in the DAC_AUTOCR register. DMA requests must also be enabled (DMAEN = 1).

When the AUTOMODE bit is set, each hardware trigger signal generates an AHB clock request to the RCC. Once the peripheral receives the AHB clock, the content of the DAC_DHRx register is loaded into DAC_DOR register and a DMA request is generated. When the DMA transaction is complete, the DAC deasserts the AHB clock request and waits for a new trigger event.

When the sample and hold mode is selected, the dac_ker_ck low-power clock must be enabled by the RCC.

DMA transfers in autonomous mode are performed following the sequence described below:

1. The DAC outputs the voltage on a GPIO or on an on-chip peripheral (dac_ker_ck and dac_hclk are not required).
2. The DAC receives a hardware trigger from another peripheral.
3. The DAC asserts the clock request.
4. The DAC loads the DAC_DHRx register into DAC_DOR register.
5. The DAC generates a DMA request.
6. The DMA transfers the new data from memory to DAC_DHRx registers.
7. The DAC deasserts the clock request.

To initialize the DAC to operate autonomously in Stop mode, follow the sequence below:

1. Enable the DAC clock autonomous mode in the RCC.
2. Select the DAC kernel clock in the RCC.
3. Enable dac_hold_ck clock for the DAC in the RCC.
4. Select a sample and hold mode through MODEx bit.
5. Configure the sample and hold mode by setting TSAMPLEx[9:0], THOLDx[9:0], TREFRESHx[7:0] bits.
6. Load the target value into DAC_DHRx register.
7. Set TENx bit to output the DAC value.
8. Configure the trigger setting through TSEL[3:0] bits.
9. Set DMAENx bit and configure the DMA interface.
10. Set the AUTOMODE bit.

Timing uncertainty of DAC_DHRx to DAC_DOR transfer

After each trigger event, the data contained in DAC_DHRx register is transferred to the DAC_DOR register. Since this transfer is based on AHB clock, the transfer timing depends on the clock availability.

When the AHB clock is stopped, a minimum time is required to restart it. This time depends on the clock source.

23.5 DAC in low-power modes

Table 202. Effect of low-power modes on DAC

Mode	Description
Sleep	No effect, DAC used with DMA
Stop 0[1]	The DAC remains functional and can perform DMA transfers in sample and hold mode.
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby or Shutdown mode.
Shutdown	

1. Refer to *Section 23.3: DAC implementation* for information on the Stop modes supported by the DAC peripheral.

23.6 DAC interrupts

Table 203. DAC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
DAC	DMA underrun	DMAUDRx	DMAUDRIEx	Write DMAUDRx = 1	Yes	No	No

23.7 DAC registers

Refer to *Section 1 on page 87* for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

23.7.1 DAC control register (DAC_CR)

Address offset: 0x00

	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in normal operating mode

1: DAC channel2 in calibration mode

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 28 **DMAEN2**: DAC channel2 DMA enable
This bit is set and cleared by software.
0: DAC channel2 DMA mode disabled
1: DAC channel2 DMA mode enabled
Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095
Note: These bits are available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable
These bits are set/reset by software.
00: wave generation disabled
01: Noise wave generation enabled
10: Triangle wave generation enabled
11: Reserved
Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)
These bits are available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection
These bits select the external event used to trigger DAC channel2
0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15
Refer to the trigger selection tables in for details on trigger configuration and mapping.
Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).
These bits are available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register

1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

Note: When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.

These bits are available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled

1: DAC channel2 enabled

Note: These bits are available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel1 calibration enable

This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel1 in normal operating mode

1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
00: wave generation disabled
01: Noise wave generation enabled
10: Triangle wave generation enabled
11: Reserved
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bits 5:2 **TSEL1[3:0]**: DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
Refer to the trigger selection tables in for details on trigger configuration and mapping.
Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1**: DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register
Note: When software trigger is selected, the transfer from the DAC_DHR1 *register to the DAC_DOR1 register takes only one dac_hclk clock cycle.*

Bit 0 **EN1**: DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

23.7.2 DAC software trigger register (DAC_SWTRGR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWTRIG2	SWTRIG1
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

23.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DHRB[11:0]**: DAC channel1 12-bit right-aligned data B

These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software. They specify 12-bit data for DAC channel1.

23.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1)

Address offset: 0x0C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:20 **DACC1DHRB[11:0]**: DAC channel1 12-bit left-aligned data B
These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data
These bits are written by software.
They specify 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

23.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1)

Address offset: 0x10

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC1DHRB[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1.

23.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2)

This register is available only on dual-channel DACs. Refer to *Section 23.3: DAC implementation*.

Address offset: 0x14

Reset value: 0x0000 0000

				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DORB[11:0]**: DAC channel1 data output
These bits are read-only. They contain data output for DAC channel1 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DOR[11:0]**: DAC channel1 data output
These bits are read-only, they contain data output for DAC channel1.

23.7.13 DAC channel2 data output register (DAC_DOR2)

This register is available only on dual-channel DACs. Refer to *Section 23.3: DAC implementation*.

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DORB[11:0]**: DAC channel2 data output
These bits are read-only. They contain data output for DAC channel2 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DOR[11:0]**: DAC channel2 data output
These bits are read-only, they contain data output for DAC channel2.

23.7.14 DAC status register (DAC_SR)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWST2	CAL_ FLAG2	DMAU DR2	DORST AT2	DAC2R DY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	rc_w1	r	r											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BWST1	CAL_ FLAG1	DMAU DR1	DORST AT1	DAC1R DY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	rc_w1	r	r											

Bit 31 **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2, It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0:There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written

1:There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value

1: calibration trimming value is equal or greater than the offset correction value

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2

1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 28 **DORSTAT2**: DAC channel2 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 27 **DAC2RDY**: DAC channel2 ready status bit

This bit is set and cleared by hardware.

0: DAC channel2 is not yet ready to accept the trigger nor output data

1: DAC channel2 is ready to accept the trigger or output data

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bits 26:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag

This bit is systematically set just after sample and hold mode enable and is set each time the software writes the register DAC_SHSR1, It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0:There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written

1:There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value

1: calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1

1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 **DORSTAT1**: DAC channel1 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Bit 11 **DAC1RDY**: DAC channel1 ready status bit

This bit is set and cleared by hardware.

0: DAC channel1 is not yet ready to accept the trigger nor output data

1: DAC channel1 is ready to accept the trigger or output data

Bits 10:0 Reserved, must be kept at reset value.

23.7.15 DAC calibration control register (DAC_CCR)

Address offset: 0x38

Reset value: 0x00XX 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM2[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM1[4:0]				
											rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **OTRIM2[4:0]**: DAC channel2 offset trimming value

These bits are available only on dual-channel DACs. Refer to *Section 23.3: DAC implementation*.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **OTRIM1[4:0]**: DAC channel1 offset trimming value

23.7.16 DAC mode control register (DAC_MCR)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SINFORMAT2	DMADOUBLE2	Res.	Res.	Res.	Res.	Res.	MODE2[2:0]		
						rw	rw						rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HFSEL[1:0]		Res.	Res.	Res.	Res.	SINFORMAT1	DMADOUBLE1	Res.	Res.	Res.	Res.	Res.	MODE1[2:0]		
rw	rw					rw	rw						rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SINFORMAT2**: Enable signed format for DAC channel2

This bit is set and cleared by software.

0: Input data is in unsigned format

1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bit 24 **DMADOUBLE2**: DAC channel2 DMA double data mode

This bit is set and cleared by software.

0: DMA normal mode selected

1: DMA double data mode selected

Note: This bit is available only on dual-channel DACs. Refer to Section 23.3: DAC implementation.

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE2[2:0]:** DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

– DAC channel2 in normal mode

000: DAC channel2 is connected to external pin with Buffer enabled

001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled

010: DAC channel2 is connected to external pin with buffer disabled

011: DAC channel2 is connected to on chip peripherals with Buffer disabled

– DAC channel2 in sample and hold mode

100: DAC channel2 is connected to external pin with Buffer enabled

101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled

110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled

111: DAC channel2 is connected to on chip peripherals with Buffer disabled

Note: This register can be modified only when EN2 = 0.

Refer to Section 23.3: DAC implementation for the availability of DAC channel2.

Bits 15:14 **HFSEL[1:0]**: High frequency interface mode selection
00: High frequency interface mode disabled
01: High frequency interface mode enabled for AHB clock frequency > 80 MHz
10: High frequency interface mode enabled for AHB clock frequency >160 MHz
11: Reserved

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SINFORMAT1**: Enable signed format for DAC channel1
This bit is set and cleared by software.
0: Input data is in unsigned format
1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Bit 8 **DMADOUBLE1**: DAC channel1 DMA double data mode
This bit is set and cleared by software.
0: DMA normal mode selected
1: DMA double data mode selected

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]:** DAC channel1 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.
They can be set and cleared by software to select the DAC channel1 mode:
– DAC channel1 in normal mode
000: DAC channel1 is connected to external pin with Buffer enabled
001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
010: DAC channel1 is connected to external pin with Buffer disabled
011: DAC channel1 is connected to on chip peripherals with Buffer disabled
– DAC channel1 in sample & hold mode
100: DAC channel1 is connected to external pin with Buffer enabled
101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
111: DAC channel1 is connected to on chip peripherals with Buffer disabled
Note: This register can be modified only when EN1 = 0.

23.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]:** DAC channel1 sample time (only valid in sample and hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. in the latter case, the write can be done only when BWST1 of DAC_SR register is low, If BWST1 = 1, the write operation is ignored.

*Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (*TSAMPLE1[9:0] + 1) x *LSI/LSE clock period.*

23.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to *Section 23.3: DAC implementation*.

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE2[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE2[9:0]:** DAC channel2 sample time (only valid in sample and hold mode)
These bits can be written when the DAC channel2 is disabled or also during normal operation. in the latter case, the write can be done only when BWST2 of DAC_SR register is low, if BWST2 = 1, the write operation is ignored.

*Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (*TSAMPLE1[9:0] + 1) x *LSI/LSE clock period.*

23.7.19 DAC sample and hold time register (DAC_SHHR)

Address offset: 0x48

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	THOLD2[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	THOLD1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **THOLD2[9:0]:** DAC channel2 hold time (only valid in sample and hold mode).
Hold time = (THOLD[9:0]) x LSI/LSE clock period
These bits are available only on dual-channel DACs. Refer to *Section 23.3: DAC implementation*.
Note: This register can be modified only when EN2 = 0.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **THOLD1[9:0]:** DAC channel1 hold time (only valid in sample and hold mode)
Hold time = (THOLD[9:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

23.7.20 DAC sample and hold refresh time register (DAC_SHRR)

Address offset: 0x4C

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH2[7:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH1[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TREFRESH2[7:0]:** DAC channel2 refresh time (only valid in sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
These bits are available only on dual-channel DACs. Refer to *Section 23.3: DAC implementation*.
Note: This register can be modified only when EN2 = 0.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **TREFRESH1[7:0]:** DAC channel1 refresh time (only valid in sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

23.7.21 DAC autonomous mode control register (DAC_AUTOCR)

Address offset: 0x54

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

24 Voltage reference buffer (VREFBUF)

24.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for the on-chip ADCs and DACs, and also as voltage reference for external components through the VREF+ pin.

24.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

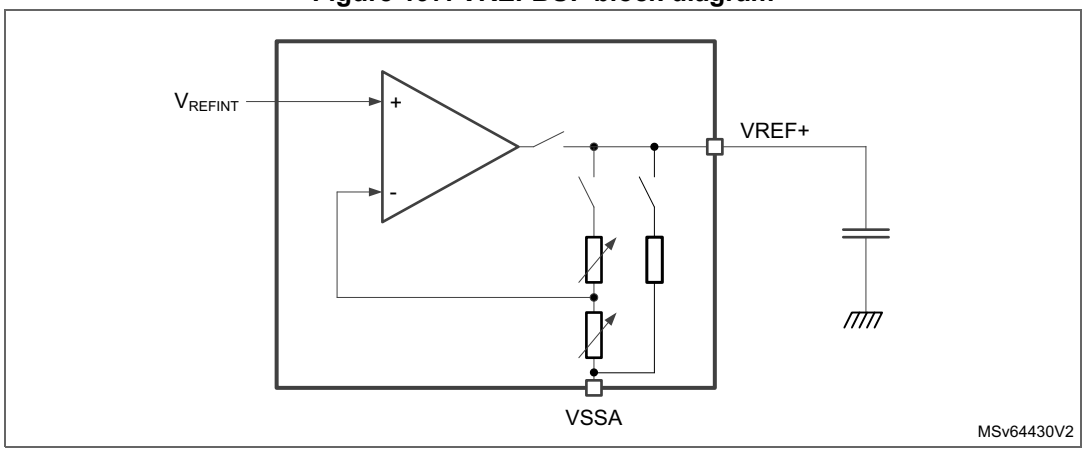

Table 205. VREFBUF typical values

Symbol	Value
VREFBUF0	1.5 V
VREFBUF1	1.8 V
VREFBUF2	2.048 V
VREFBUF3	2.5 V

Note: Refer to the product datasheet for more details.

24.3 VREFBUF functional description

Figure 197. VREFBUF block diagram

The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference V_{REFINT}. The VREFBUF supports four voltages[a], which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected
- VRS = 001: VREFBUF1 voltage selected
- VRS = 010: VREFBUF2 voltage selected
- VRS = 011: VREFBUF3 voltage selected

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

Table 206. VREF buffer modes

ENVR	HIZ	VREF buffer configuration
0	0	VREFBUF buffer off mode: – V_{REF+} pin pulled-down to V_{SSA}
0	1	External voltage reference mode (default value): – VREFBUF buffer off – V_{REF+} pin input mode
1	0	Internal voltage reference mode: – VREFBUF buffer on – V_{REF+} pin connected to VREFBUF buffer output
1	1	Hold mode: – VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor – VRR detection disabled and VRR bit keeps last state

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

24.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

a. The minimum V_{DDA} voltage depends on VRS setting, refer to the product datasheet.

24.5 VREFBUF registers

24.5.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VRS[2:0]			VRR	Res.	HIZ	ENVR
									rw	rw	rw	r		rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

VRS = 000: VREFBUF0 voltage selected.
VRS = 001: VREFBUF1 voltage selected.
VRS = 010: VREFBUF2 voltage selected.
VRS = 011: VREFBUF3 voltage selected.
Others: Reserved

Note: Refer to the product datasheet for each VREFBUFx voltage setting value.
The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3 **VRR:** Voltage reference buffer ready

0: the voltage reference buffer output is not ready.
1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ:** High impedance mode

This bit controls the analog switch to connect or not the V_{REF+} pin.
0: V_{REF+} pin is internally connected to the voltage reference buffer output.
1: V_{REF+} pin is high impedance.
Refer to *Table 206: VREF buffer modes* for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR:** Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.
0: Internal voltage reference mode disable (external voltage reference mode).
1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

24.5.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRIM[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]**: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:

TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the flash memory during the production test.

VRS change:

TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the flash memory during the production test.

Write in TRIM[5:0]:

User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

24.5.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Table 207. VREFBUF register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Reset value																											x	x	x	x	x	x

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

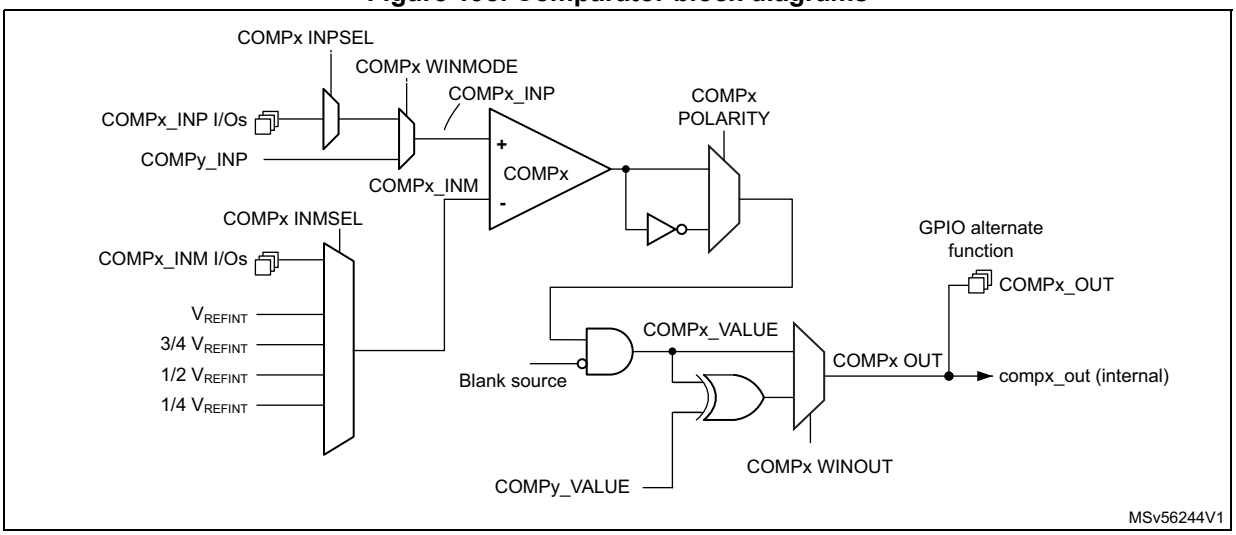
25 Comparator (COMP)

25.1 Introduction

The device embeds two ultra-low-power comparators COMP1 and COMP2.

These comparators can be used for a variety of functions including:

- Wake-up from low-power mode triggered by an analog signal
- Analog signal conditioning
- Cycle-by-cycle current control loop when combined with a PWM output from a timer



25.2 COMP main features

- Each comparator has configurable plus and minus inputs used for flexible voltage selection:
  - Multiplexed I/O pins
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by a scaler (buffered voltage divider)
- Programmable hysteresis
- Programmable speed/consumption
- Outputs that can be redirected to an I/O or to timer inputs for triggering break events for fast PWM shutdowns
- Comparator outputs with blanking source
- Comparators that can be combined as a window comparator
- Interrupt generation capability for each comparator with wake-up from Sleep and Stop modes (through the EXTI controller)

25.3 COMP functional description

25.3.1 COMP block diagram

Figure 198. Comparator block diagrams

25.3.2 COMP pins and internal signals

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:

- Emergency shut-down of PWM signals, using BKIN and BKIN2 inputs
- Cycle-by-cycle current control, using OCREF_CLR inputs
- Input capture for timing measures

The comparator output can be simultaneously redirected internally and externally.

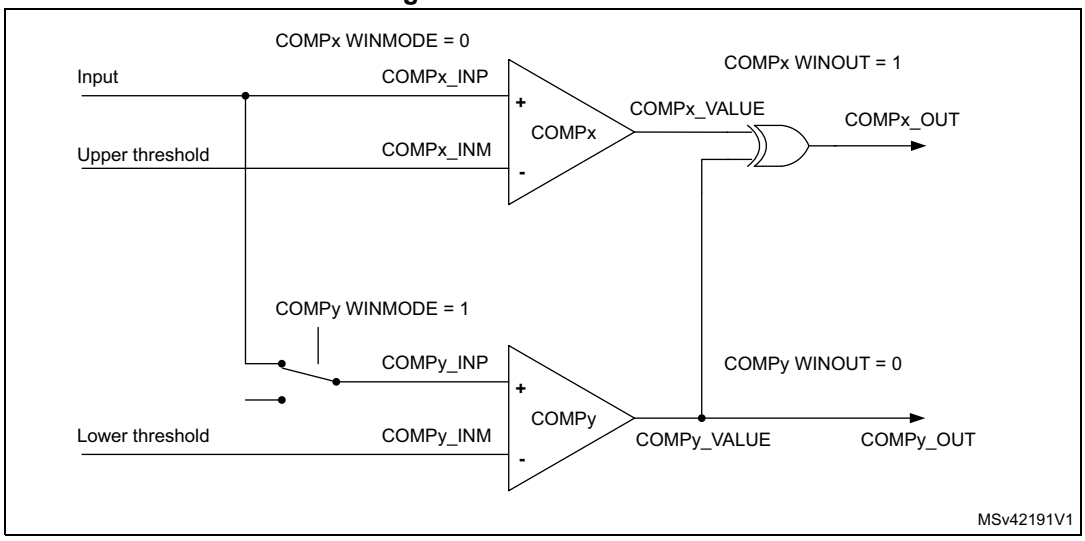
25.3.3 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, the comparator programming must not be altered in case of spurious register access or program counter corruption. For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPxLOCK bit can be set to 1. This causes the whole COMPx_CSR register to become read-only, including the COMPxLOCK bit.

The write protection can be reset only by an MCU reset.



25.3.4 Window comparator

The purpose of the window comparator is to monitor the analog voltage if it is within the voltage range defined by the lower and upper thresholds.

The two embedded comparators can be used to create a window comparator. The monitored analog voltage is connected to the noninverting (plus) inputs of the two comparators connected together. The upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators.

Two noninverting inputs can be connected internally by enabling the WINMODE bit to save one I/O for other purposes.

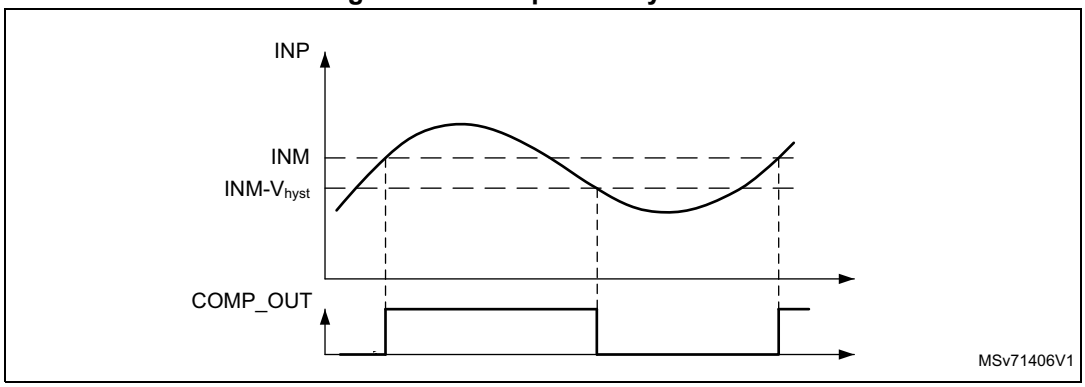


Figure 199. Window mode

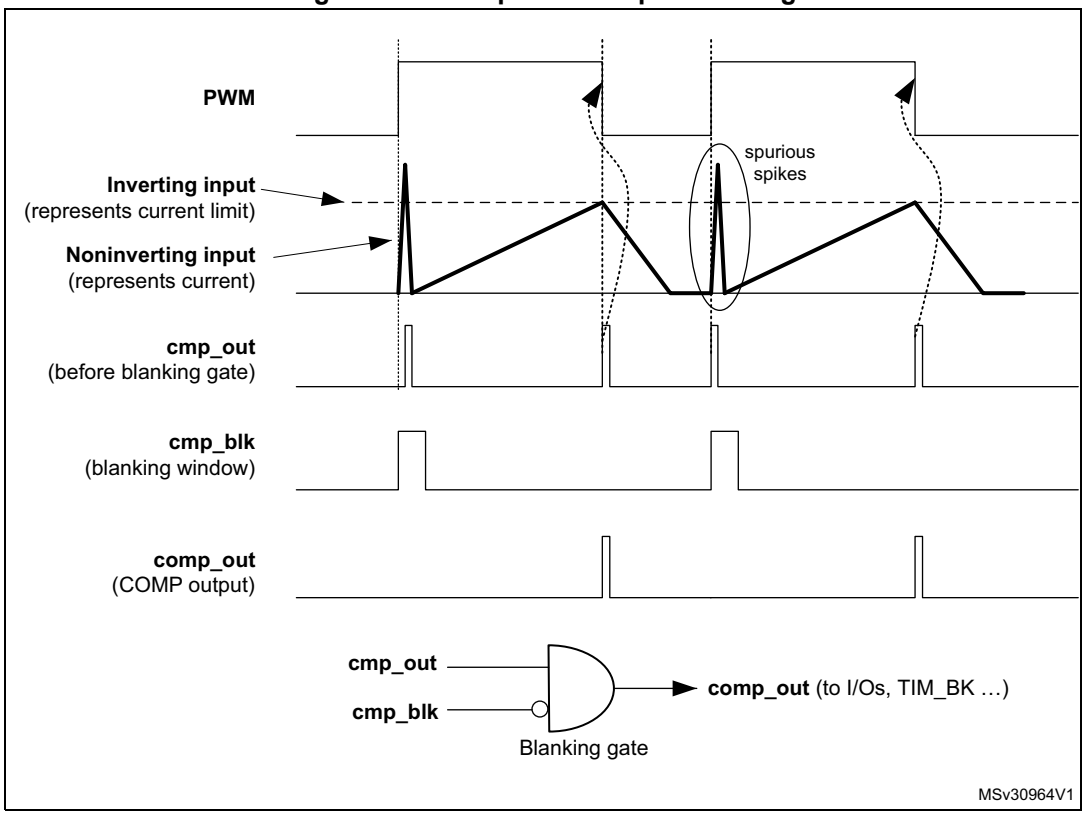
25.3.5 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting a low-power mode) to be able to force the hysteresis value using external components.

Figure 200. Comparator hysteresis



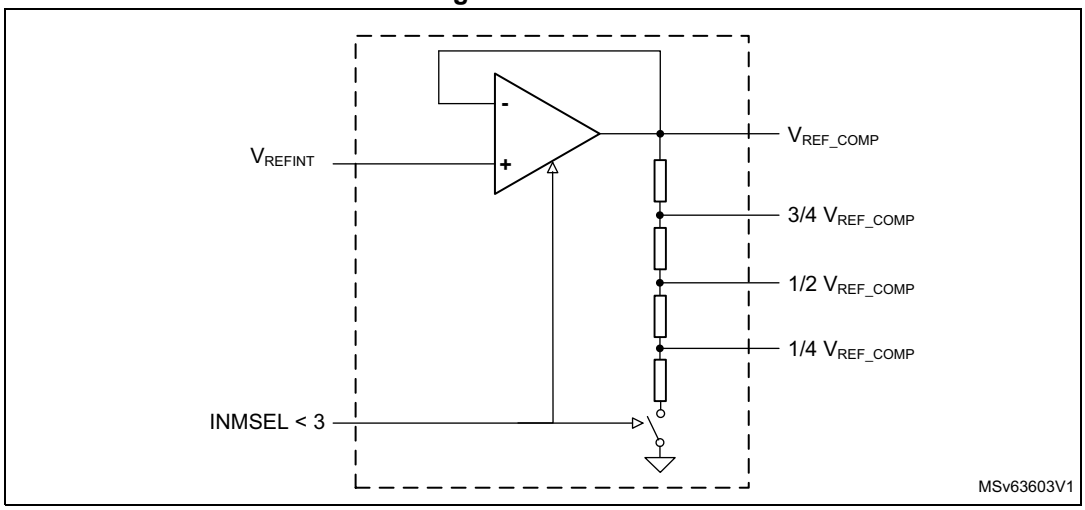
25.3.6 Comparator output-blanking function

The blanking function prevents the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). This blanking function consists of a selection of a blanking window that is a timer output compare signal. The selection is done by the software (refer to the comparator register description for possible blanking signals).

The complementary of the blanking signal is AND-ed with the comparator output to provide the wanted comparator output (see the example in *Figure 201*).

Figure 201. Comparator output blanking

25.3.7 COMP power and speed modes



COMP1 and COMP2 power consumption versus propagation delay can be adjusted to have the optimum trade-off for a given application.

25.3.8 Scaler function

The scaler block provides the different voltage reference levels to the comparator inputs. This block is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference.The amplifier and the resistor bridge are enabled by setting the INMSEL value in the COMP_CFGRx registers, to connect the corresponding inverting input to the scaler output.

When the divided voltage is not used, the resistor bridge and the amplifier are disabled to reduce the consumption. When the resistor bridge is disconnected, the 1/4 VREF_COMP, 1/2 VREF_COMP, and 3/4 VREF_COMP levels are equal to VREF_COMP.

Figure 202. Scaler

25.4 COMP in low-power modes

Table 214. Comparator behavior in the low-power modes

Mode	Description
Sleep	No effect on the comparators. Comparator interrupts cause the device to exit Sleep mode.
Stop	No effect on the comparators. Comparator interrupts cause the device to exit Stop mode.
Standby	COMP registers are powered down and must be reinitialized after exiting Standby mode.

25.5 COMP interrupts

The comparator outputs are internally connected to the extended interrupts and events controller (EXTI). Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit the low-power modes.

Refer to *Section 17: Extended interrupts and event controller (EXTI)* for more details.

To enable the COMPx interrupt, follow this sequence:

1. Configure and enable the EXTI line corresponding to the COMPx output event in interrupt mode and select the rising, falling or both edges sensitivity.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

Table 215. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Exit Sleep mode	Exit Stop modes	Exit Standby mode
COMP1 output	In EXTI	Through EXTI	Yes	Yes	No
COMP2 output	In EXTI	Through EXTI	Yes	Yes	No

25.6 COMP registers

25.6.1 COMP1 control and status register (COMP1_CSR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	VALUE	Res.	Res.	Res.	Res.	Res.	BLANKSEL[4:0]					PWRMODE[1:0]		HYST[1:0]	
rs	r						rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw			rw		rw	rw	rw	rw	rw	rw				rw

Bit 31 **LOCK:** COMP1_CSR register lock

This bit is set by the software and cleared by reset. It locks the whole content of COMP1_CSR.

0: COMP1_CSR read/write bits can be written by software.

1: COMP1_CSR bits can be read but not written by software.

Bit 30 **VALUE:** COMP1 output status

This bit is read-only. It reflects the level of the COMP1 output after the polarity selector and blanking (see *Figure 201: Comparator output blanking*).

Bits 29:25 Reserved, must be kept at reset value.

Bits 24:20 **BLANKSEL[4:0]:** COMP1 blanking source selector

This bitfield is controlled by software (if not locked), and selects the blanking source.

00000: None (no blanking)

00001: tim1_oc5

00010: tim2_oc3

Others: Reserved

Bits 19:18 **PWRMODE[1:0]:** COMP1 power mode selector

This bitfield is controlled by software (if not locked). It selects the power consumption and, as a consequence, the speed of the COMP1.

00: High speed

01: Intermediate speed and power

10: Medium speed and power

11: Ultra-low-power

Bits 17:16 **HYST[1:0]:** COMP1 hysteresis selector
This bitfield is controlled by software (if not locked). It selects the COMP1 hysteresis.
00: None
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 15 **POLARITY:** COMP1 polarity selector
This bit is controlled by software (if not locked). It selects the COMP1 output polarity.
0: Noninverted
1: Inverted

Bit 14 **WINOUT:** COMP1 output selector
This bit is controlled by the software (if not locked). It selects the COMP1 output.
0: COMP1_VALUE
1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see *Figure 199: Window mode*)

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WINMODE**: COMP1 noninverting input selector for window mode
This bit is controlled by software (if not locked). It selects the signal for the COMP1_INP input of the COMP1.
0: Signal selected with INPSEL[1:0]
1: COMP2_INP signal of COMP2 (required for window mode, see *Figure 199: Window mode*)

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **INPSEL[1:0]**: COMP1 signal selector for noninverting input
This bitfield is controlled by software (if not locked). It selects the signal for the noninverting input COMP1_INP (see *Table 210: COMP2 noninverting input assignment* for the assignment).

Bits 7:4 **INMSEL[3:0]**: COMP1 signal selector for inverting input INM
This bitfield is controlled by software (if not locked). It selects the signal for the inverting input COMP1_INM (see *Table 209: COMP1 inverting input assignment* for the assignment).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **EN:** COMP1 enable
This bit is controlled by the software (if not locked). It enables COMP1.
0: COMP1 disabled
1: COMP1 enabled

25.6.2 COMP2 control and status register (COMP2_CSR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	VALUE	Res.	Res.	Res.	Res.	Res.	BLANKSEL[4:0]					PWRMODE[1:0]		HYST[1:0]	
rs	r						rw	rw	rw	rw	rw	rw	rw	rw	rw

POLARITY	WINOUT	Res.	Res.	WINMODE	Res.	INPSEL[1:0]		INMSEL[3:0]				Res.	Res.	Res.	EN
rw	rw			rw		rw	rw	rw	rw	rw	rw				rw

Bit 31 **LOCK:** COMP2_CSR register lock

This bit is set by software and cleared by reset. It locks the whole content of COMP2_CSR.
0: COMP2_CSR read/write bits can be written by software.
1: COMP2_CSR bits can be read but not written by software.

Bit 30 **VALUE:** COMP2 output status

This bit is read-only. It reflects the level of the COMP2 output after the polarity selector and blanking (see *Figure 201: Comparator output blanking*).

Bits 29:25 Reserved, must be kept at reset value.

Bits 24:20 **BLANKSEL[4:0]:** COMP2 blanking source selector

This bitfield is controlled by software (if not locked), and selects the blanking source.
00000: None (no blanking)
00001: tim3_oc4
Others: Reserved

Bits 19:18 **PWRMODE[1:0]:** COMP2 power mode selector

This bitfield is controlled by software (if not locked). It selects the power consumption and, as a consequence, the speed of the COMP2.
00: High speed
01: Intermediate speed and power
10: Medium speed and power
11: Ultra-low-power

Bits 17:16 **HYST[1:0]:** COMP2 hysteresis selector

This bitfield is controlled by software (if not locked). It selects the COMP2 hysteresis.
00: None
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 15 **POLARITY:** COMP2 polarity selector

This bit is controlled by software (if not locked). It selects the COMP2 output polarity.
0: Noninverted
1: Inverted

Bit 14 **WINOUT:** COMP2 output selector

This bit is controlled by software (if not locked). It selects the COMP2 output.
0: COMP2_VALUE
1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see *Figure 199: Window mode*)

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WINMODE**: COMP2 noninverting input selector for window mode

This bit is controlled by software (if not locked). It selects the signal for the COMP2_INP input of the COMP2.

0: Signal selected with INPSEL[1:0]

1: COMP1_INP signal of COMP1 (required for window mode, see *Figure 199: Window mode*)

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **INPSEL[1:0]**: COMP2 signal selector for noninverting input

This bitfield is controlled by software (if not locked). It selects the signal for the noninverting input COMP2_INP (see *Figure 210: COMP2 noninverting input assignment* for the assignment).

Bits 7:4 **INMSEL[3:0]**: COMP2 signal selector for inverting input INM

This bitfield is controlled by software (if not locked). It selects the signal for the inverting input COMP2_INM (see *Figure 209: COMP1 inverting input assignment* for the assignment).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **EN:** COMP2 enable

This bit is controlled by software (if not locked). It enables COMP2.

0: COMP2 disabled

1: COMP2 enabled

25.6.3 COMP register map

Table 216. COMP register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

26 Operational amplifier (OPAMP)

26.1 OPAMP introduction

STM32U3 series devices embed two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, this enables any type of external interconnections. The operational amplifier can be configured internally as a follower or as an amplifier with a noninverting gain ranging from 2 to 16.

The positive input can be connected to the internal DAC.

The output can be connected to the internal ADC.

26.2 OPAMP main features

- Rail-to-rail input voltage range
- Low input bias current
- Low input offset voltage
- Low-power mode
- High-speed mode to achieve a better slew rate
- Fast wake-up time
- Gain bandwidth of 1.6 MHz

26.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are three functional modes: the low-power mode, the high-speed mode, and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in the *Section 26.3.3*.

26.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in RCC_APB1ENR1, and OPAMPSLPEN bit in RCC_APB1SLPENR1).

The OPAEN bit in OPAMPx_CSR enables and disables the OPAMP operation. The OPAMP registers configurations can be changed when the OPAEN bit is set in OPAMPx_CSR. However, it can create spurious effects (noise, glitch, overshoot, or saturation). If the configuration is changed, the application firmware must take care of these spurious effects (such as ignore the ADC result on the OPAMP output).

When the OPAMP output is no more needed, the OPAMP can be disabled to save power. All the configurations previously set (including the calibration) are maintained while the OPAMP is disabled.

26.3.2 Initial configuration

The OPAMP default configuration is a functional mode where the three IOs are connected to external pins. In the default mode, the OPAMP uses the factory trimming values (see “electrical characteristics” section of the datasheet for factory trimming conditions. Usually the temperature is 30 °C and the voltage is 3 V). The trimming values can be adjusted (see *Section 26.3.5*). The default configuration uses the normal mode that provides the standard performance. The OPALPM bit in OPAMPx_CSR can be set in order to switch the OPAMP to low-power mode and reduced performance. Normal, low-power, and high-speed modes characteristics are defined in the “electrical characteristics” section of the datasheet. Before utilization, the OPA_RANGE bit in OPAMP1_CSR must be set to 1.

As soon as the OPAEN bit in OPAMPx_CSR is set, the OPAMP is functional. The two input pins and the output pin are connected as defined in *Section 26.3.3* and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

26.3.3 Signal routing

The routing for the OPAMP pins is determined by the OPAMPx_CSR register.

The connections of the operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

Table 217. Operational amplifier possible connections

Signal	Pin	Internal	comment
OPAMP1_VINM	PA1	ADC1_IN4, OPAMP1_OUT or PGA	Controlled by OPAMODE and VM_SEL
OPAMP1_VINP	PA0	ADC1_IN3, dac1_out1	Controlled by bit VP_SEL
OPAMP1_VOUT	PA3	ADC1_IN6 COMP1_INP4	The pin is connected when the OPAMP is enabled. The ADC input is controlled by the ADC.
OPAMP2_VINM	PA7	ADC1_IN10, ADC2_IN6, OPAMP2_OUT or PGA	Controlled by bits OPAMODE and VM_SEL
OPAMP2_VINP	PA6	ADC1_IN9, ADC2_IN5, dac1_out2	Controlled by bit VP_SEL
OPAMP2_VOUT	PB0	ADC1_IN13 ADC2_IN9	The pin is connected when the OPAMP is enabled. The ADC input is controlled by the ADC.

26.3.4 OPAMP modes

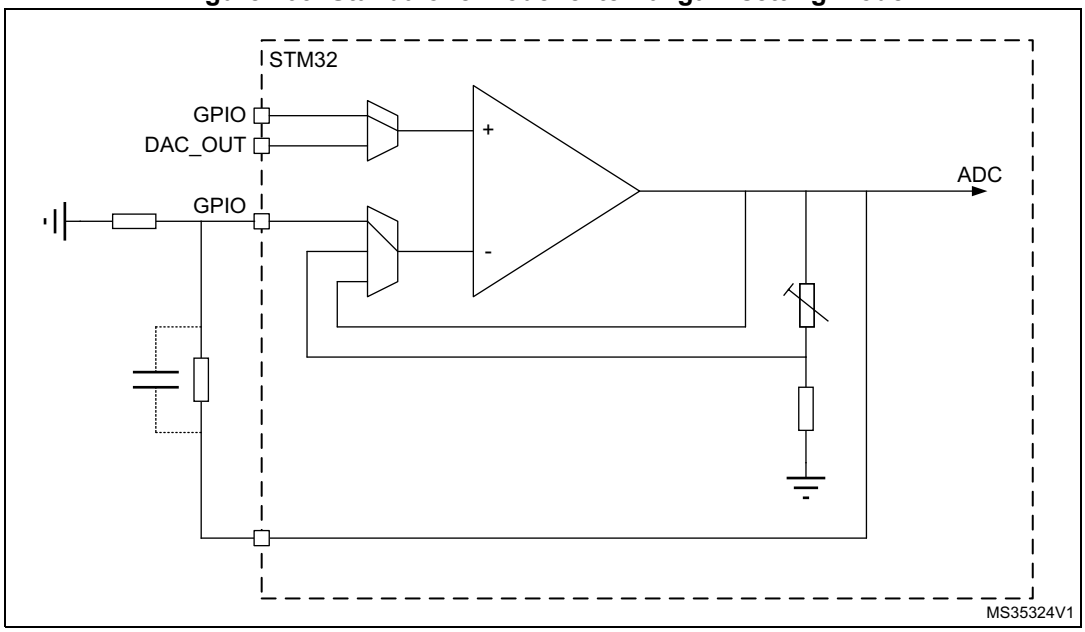
The OPAMP inputs and outputs are all accessible on terminals. The amplifiers can be used in the following configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

The amplifier output pin is directly connected to the output pad to minimize the output impedance. It cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the ADC channel.

The impedance of the signal must be maintained below a level that avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Refer to the “electrical characteristics” section in the datasheet for further details.

Standalone mode (external gain setting mode)



The procedure to use the OPAMP in standalone mode is detailed below:

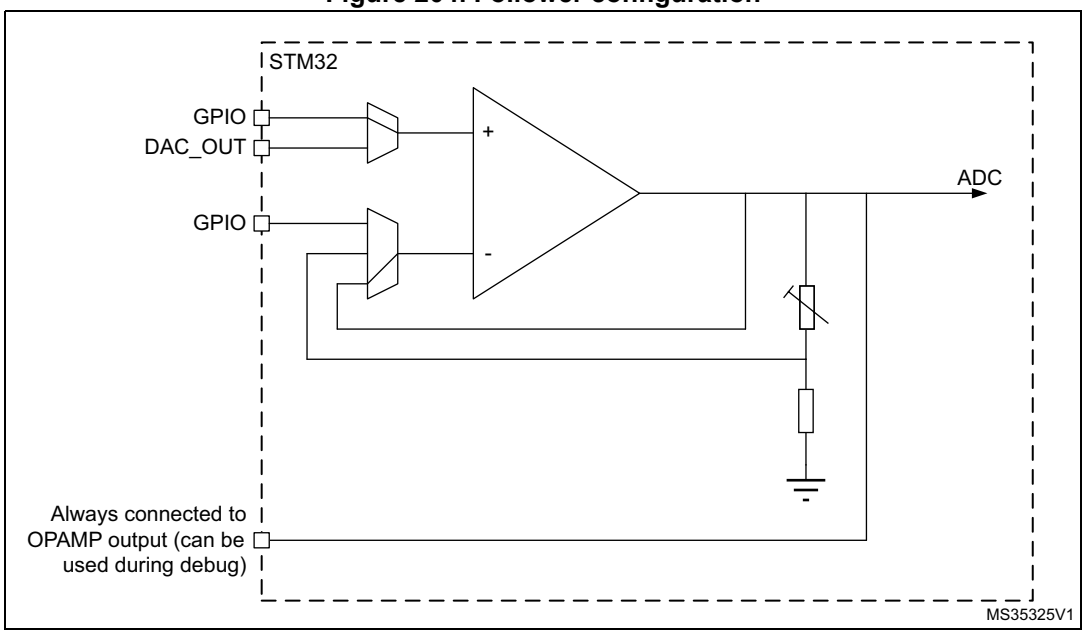
1. Keep default value of OPAMPx_CSR and the default state of GPIOx_MODER.
2. As soon as OPAEN is set in OPAMPx_CSR, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (standard performance). The OPAMP behavior can be changed with the following bits in OPAMPx_CSR:

- If OPALPM is set to 1, the OPAMP switches in low-power mode in order to save power.
- If OPAHSM is set to 1, the OPAMP switches in high-speed mode in order to have a high slew rate.
- If USERTRIM is set to 1, the input offset values can be trimmed.

Figure 203. Standalone mode: external gain setting mode

Follower configuration mode



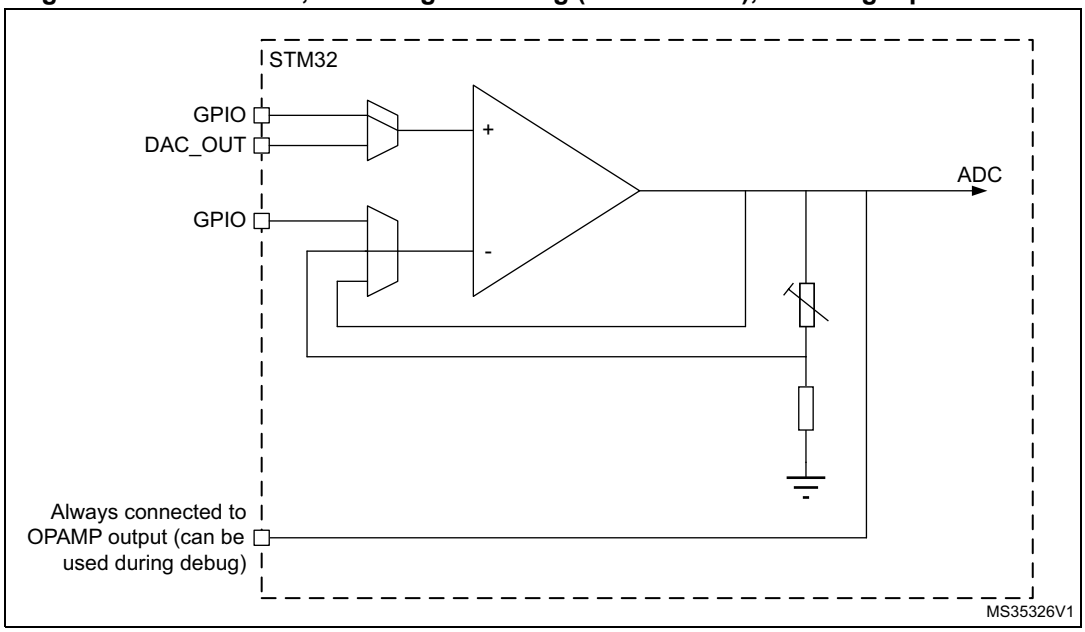
The procedure to use the OPAMP in follower mode is detailed below (all bits in OPAMPx_CSR):

1. Set OPAMODE[1:0] = 11 (internal follower).
2. Clear VP_SEL to 0 (GPIO connected to OPAMPx_VINP, named VINP in this document).
3. As soon as OPAEN is set to 1, the signal on the VINP pin is copied to the OPAMP_VOUT pin.

Note: The pin corresponding to OPAMP_VINM is free for another usage.

The signal on the OPAMP output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming that the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

Figure 204. Follower configuration



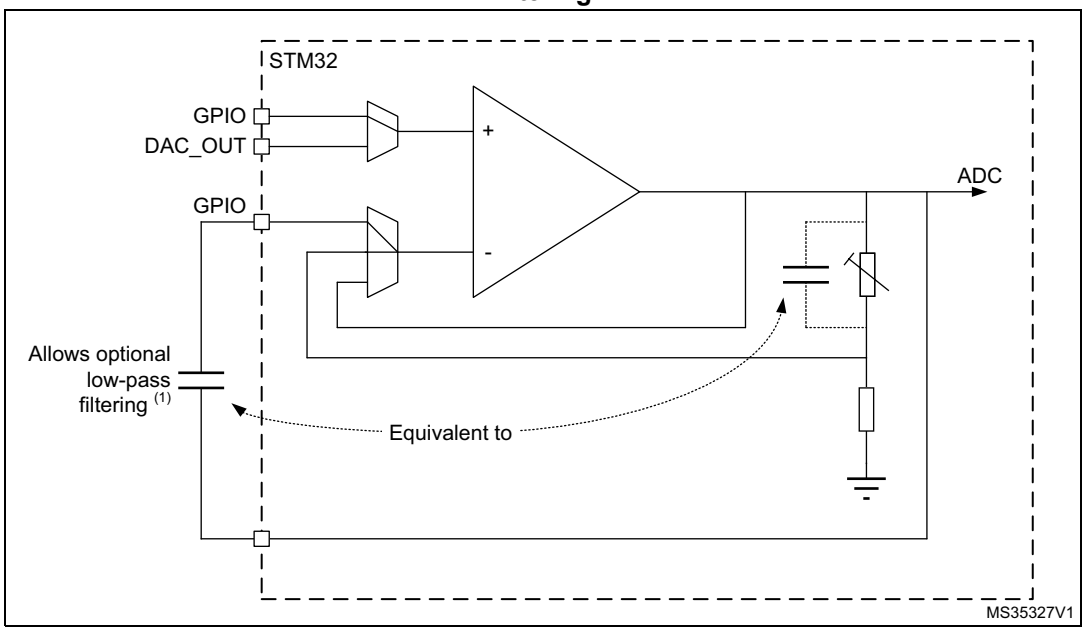
Programmable gain amplifier mode

The procedure to use the OPAMP to amplify the amplitude of an input signal is detailed below (all bits in OPAMPx_CSR):

1. Set OPAMODE[1:0] to 10 (internal PGA enabled).
2. Set PGA_GAIN[1:0] to the selected PGA gain (2, 4, 8 or 16) in OPAMPx_CSR.
3. Set VM_SEL[1:0] to 1x in OPAMPx_CSR (inverting input not externally connected).
4. Clear VP_SEL to 0 in OPAMPx_CSR (GPIO connected to VINP).
5. As soon as OPAEN is set in OPAMPx_CSR, the signal on the OPAMP_VINP pin is amplified by the selected gain, and visible on the OPAMP_VOUT pin.

Note: To avoid saturation, the input voltage must stay below V_{DDA} divided by the selected gain.

Figure 205. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used



Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external set, is detailed below (all bits in OPAMPx_CSR):

1. Configure OPAMODE[1:0] to 10 (internal PGA enabled).
2. Set PGA_GAIN[1:0] to the selected PGA gain (2, 4, 8 or 16).
3. Clear VM_SEL[1:0] to 00 or 01(GPIO connected to VINM).
4. Clear VP_SEL to 0 (GPIO connected to VINP).

Any external connection on VINP can be used in parallel with the internal PGA. For example, a capacitor can be connected between VOUT and VINM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 206. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input used for filtering

1. The gain depends on the cut-off frequency.

26.3.5 Calibration

At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each OPAMP offset can be trimmed by the user. Specific registers allow different trimming values for normal and low-power modes.

The calibration purpose is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows the inputs offset voltage to be reduced to less than ± 1.5 mV within stable voltage and temperature conditions.

For each OPAMP and each mode, two trimming values can be trimmed: one for N differential pair and one for P differential pair.

The registers used to trim the offsets for each operational amplifiers are:

- OPAMPx_OTR for normal mode
- OPAMPx_LPOTR for low-power mode

Each register is composed of five bits for P differential pair trimming, and five bits for N differential pair trimming. These are the ‘user’ values.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values, with the USERTRIM bit in OPAMPx_CSR. This bit is reset at startup and the ‘factory’ value is applied by default to the OPAMP trimming registers.

The trimming values can be changed in calibration or in functional mode.

The offset trimming registers are typically configured after the initialization of the calibration operation (CALON set to 1 in OPAMPx_CSR). When CALON = 1, the OPAMP inputs are disconnected from the functional environment.

Setting CALSEL to 1 in OPAMPx_CSR initializes the offset calibration for the P differential pair (low-voltage reference used).

Clearing CALSEL to 0 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the CALOUT bit in OPAMPx_CSR reflects the influence of the trimming value selected by CALSEL and OPALPM. When the value of CALOUT switches between two consecutive trimming values, this means that those two values are the best trimming values. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see $t_{OFFTRIM}$ max delay specification in the “electrical characteristics” section of the datasheet).

Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

When the calibration operation is done, OPAHSM must be cleared to 0 in OPAMPx_CSR.

Table 218. Operating modes and calibration

Mode	Control bits				Output	
	OPAEN	OPALPM	CALON	CALSEL	V_{OUT}	CALOUT
Normal operating mode	1	0	0	X	Analog	0
Low-power mode	1	1	0	X	Analog	0
Power down	0	X	X	X	Z	0
Offset cal high for normal mode	1	0	1	0	Analog	X
Offset cal low for normal mode	1	0	1	1	Analog	X
Offset cal high for low-power mode	1	1	1	0	Analog	X
Offset cal low for low-power mode	1	1	1	1	Analog	X

Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set OPAEN to 1 in OPAMPx_CSR to enable the OPAMP and set OPA_RANGE = 1 in OPAMP1_CSR.
2. Clear OPAHSM to 0 in OPAMPx_CSR.
3. Set CALON and USERTRIM to 1 in OPAMPx_CSR.
4. Choose a calibration mode (refer to *Table 218*). Steps 4 to 5 must be repeated four times. For the first iteration, select normal mode, offset cal high (N differential pair), with OPALPM = 0 and CALSEL = 0 in OPAMPx_CSR.
5. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 0, until CALOUT changes to 1 in OPAMPx_CSR.

   Between the write to OPAMP_OTR and the read of the CALOUT value, make sure to wait for the $t_{OFFTRIM}$ max delay specified in the “electrical characteristics” section of the datasheet, to get the correct CALOUT value.

   The commutation means that the offset is correctly compensated and that the corresponding trim code must be saved in OPAMP_OTR.

6. Repeat steps 4 to 5 for:
   – Normal mode and offset cal low
   – Low-power mode and offset cal high
   – Low-power mode and offset cal low

   If a mode is not used, the corresponding calibration can be skipped.

All OPAMPs can be calibrated at the same time.

Note: During the whole calibration phase:

- *The external connection of the OPAMP output must not pull up or down currents higher than 500 µA.*
- *OPAMODE[1:0] must be set up to 00 or 01 (PGA disable) or 11 (internal follower).*

26.4 OPAMP low-power modes

Table 219. Effect of low-power modes on the OPAMP

Mode	Description
Sleep	No effect.
Stop0/1	No effect, OPAMP registers content is kept.
Stop2/3	The OPAMP is disabled; the register content is kept.
Standby	The OPAMP registers are powered down and must be re-initialized after exiting Standby mode.

26.5 OPAMP registers

26.5.1 OPAMP1 control/status register (OPAMP1_CSR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CALOUT	USERTRIM	CALSEL	CALON	Res.	VP_SEL	VM_SEL	Res.	Res.	Res.	PGA_GAIN[1:0]		OPAMODE[1:0]		OPALPM	OPAEN
r	rw	rw	rw		rw	rw				rw	rw	rw	rw	rw	rw

Bit 31 **OPA_RANGE:** OPAMP range setting
This bit must be set before enabling the OPAMP. This bit affects all OPAMP instances.
0: Reserved
1: OPAMP range set

Bit 30 **OPAHSM:** OPAMP high-speed mode
This bit is effective for both normal and low-power modes.
0: Normal mode (standard slew rate)
1: Increased consumption to improve the slew rate

Bits 29:16 Reserved, must be kept at reset value.

Bit 15 **CALOUT:** OPAMP calibration output
During the calibration mode, the offset is trimmed when this signal toggles.

Bit 14 **USERTRIM:** Selection of factory or user offset trimmed values
This bit is active for normal and low-power modes.
0: Factory trim code used
1: User trim code used

Bit 13 **CALSEL:** Calibration selection
0: NMOS calibration (200 mV applied on OPAMP inputs)
1: PMOS calibration (V_{DDA} - 200 mV applied on OPAMP inputs)

Bit 12 **CALON:** Calibration mode enable
0: Normal mode
1: Calibration mode (all switches opened by hardware)

Bit 11 Reserved, must be kept at reset value.

Bit 10 **VP_SEL:** Noninverted input selection
0: GPIO connected to VINP
1: DAC connected to VINP

Bit 9 **VM_SEL:** Inverting input selection
This bit is used only when OPAMODE[1:0] = 00, 01, or 10.
0: GPIO connected to VINM (valid also in PGA mode for filtering)
1: Inverting input not externally connected

Bits 8:6 Reserved, must be kept at reset value.

Bits 5:4 **PGA_GAIN[1:0]:** OPAMP programmable amplifier gain value
00: Internal PGA gain 2
01: Internal PGA gain 4
10: Internal PGA gain 8
11: Internal PGA gain 16

Bits 3:2 **OPAMODE[1:0]:** OPAMP PGA mode
00-01: Internal PGA disabled
10: Internal PGA enabled, gain programmed in PGA_GAIN
11: Internal follower

Bit 1 **OPALPM:** OPAMP low-power mode
The OPAMP must be disabled to change this configuration.
0: Normal mode
1: Low-power mode

Bit 0 **OPAEN:** OPAMP enable
0: OPAMP disabled
1: OPAMP enabled

26.5.2 OPAMP1 offset trimming register in normal mode (OPAMP1_OTR)

Address offset: 0x04

Reset value: 0x0000 XXXX

XXXX are factory trimmed values.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

27 Audio digital filter (ADF)

27.1 ADF introduction

The audio digital filter (ADF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- metering

The ADF features one digital serial interface (SITF0) and one digital filter (DFLT0) with flexible digital processing options in order to offer up to 24-bit final resolution.

The ADF serial interface supports several standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

The ADF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition, it is possible to insert a high-pass filter.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter bypass, filter order, decimation ratio. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A sound activity detector (SAD) is available for the detection of sounds or voice signals. The SAD is connected at the output of the DFLT0. Several parameters can be programmed in order to adjust properly the SAD to the sound environment. The SAD strongly reduces the power consumption by preventing the storage of samples into the system memory, as long as the observed signal does not match the programmed criteria.

The digital processing is performed using only the kernel clock. The ADF requests the bus interface clock (AHB clock) only when data must be transfered or when a specific event requests the attention of the system processor.

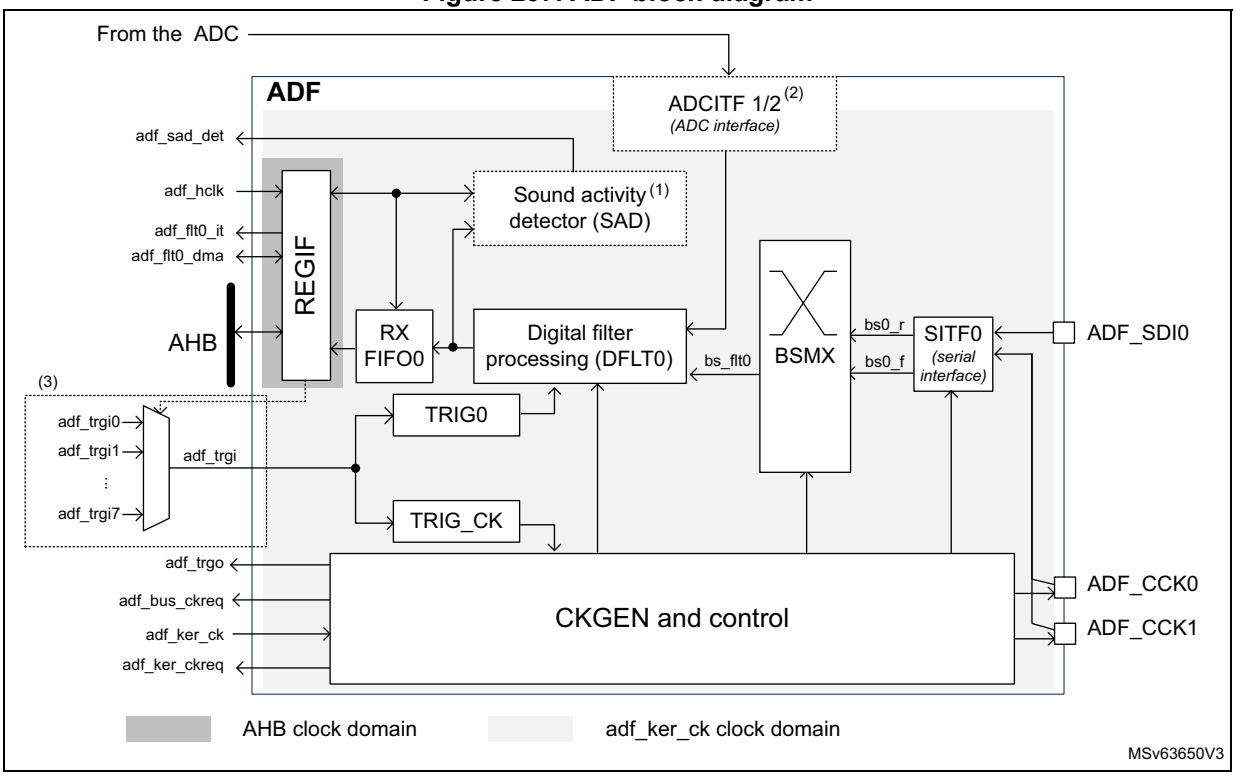
27.2 ADF main features

- AHB Interface
- 1 serial digital input:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- 1 flexible digital filter path including:
  - A MCIC filter configurable in $Sinc^4$ or $Sinc^5$ filter with an adjustable decimation ratio
  - A reshape filter to improve the out-off band rejection and in-band ripple

  - A high-pass filter to cancel the DC offset
  - Gain control
  - Saturation blocks
- Clock absence detector
- Sound activity detector
- 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay the selected bitstream
- One trigger input
- Autonomous functionality in Stop mode(s)
- DMA can be used to read the conversion data
- Interrupts services

27.3 ADF implementation

Table 221. ADF features(1)



Mode or feature	ADF1
Number of filters (DFLTx) and serial interfaces (SITFx)	1
MDF_CKIy/ADF_CKI0 connected to pins	-
Sound activity detection (SAD)	X
RXFIFO depth (number of 24-bit words)	4
ADC connected to ADCITF1	ADC1
ADC connected to ADCITF2	ADC2
Motor dedicated features (SCD, OLD, OEC, INT, snapshot, break)	-
Main path with CIC4, CIC5	X
Main path with CIC1,2, 3 or FastSinc	-
RSFLT, HPF, SAT, SCALE, DLY, Discard functions	X
Autonomous in Stop modes	X(2)

1. ‘X’ = supported, ‘-’ = not supported.
2. Only Stop 0 and Stop 1 modes.

27.4 ADF functional description

27.4.1 ADF block diagram

Figure 207. ADF block diagram

1. Refer to *Section 27.3: ADF implementation* to check if the SAD is available.
2. Refer to *Section 27.3: ADF implementation* to check if the ADCITF is available, and which ADCs are connected.
3. The number of trigger inputs depends on the product. Refer to *Table 224* for details.

27.4.2 ADF pins and internal signals

Table 222. ADF external pins

Pin name	Pin type	Remarks
ADF_SDI0	Input	Data signal from external sensors
ADF_CCKy (y = 0,1)	Input/output	Clock outputs for external sensor, or common clock input from external sensors

Table 223. ADF internal signals

Signal name	Signal type	Remarks
adf_trgi	Input	Trigger inputs to control the acquisition (see *Table 224: ADF trigger connections* for details)
adf_trgo	Output	Trigger output for synchronizing with other MDF instances

Table 223. ADF internal signals (continued)

Signal name	Signal type	Remarks
adf_flt0_dma	Input/output	DMA request/acknowledge signals for the ADF processing chain
adf_flt0_it	Output	Global interrupt signals
adf_bus_ckreq	Output	Bus interface clock request output
adf_ker_ckreq	Output	Kernel clock request output
adf_ker_ck	Input	Kernel clock input
adf_hclk	Input	AHB bus interface clock input
adf_sad_det	Output	SAD sound detection: 1 means that detecting sound
adf_adcitf1_dat[15:0]	Input	ADCITF1 data input
adf_adcitf2_dat[15:0]	Input	ADCITF2 data input

mdf_adcitf2_dat[15:0]	adc2_dat

27.4.3 Serial input interface (SITF)

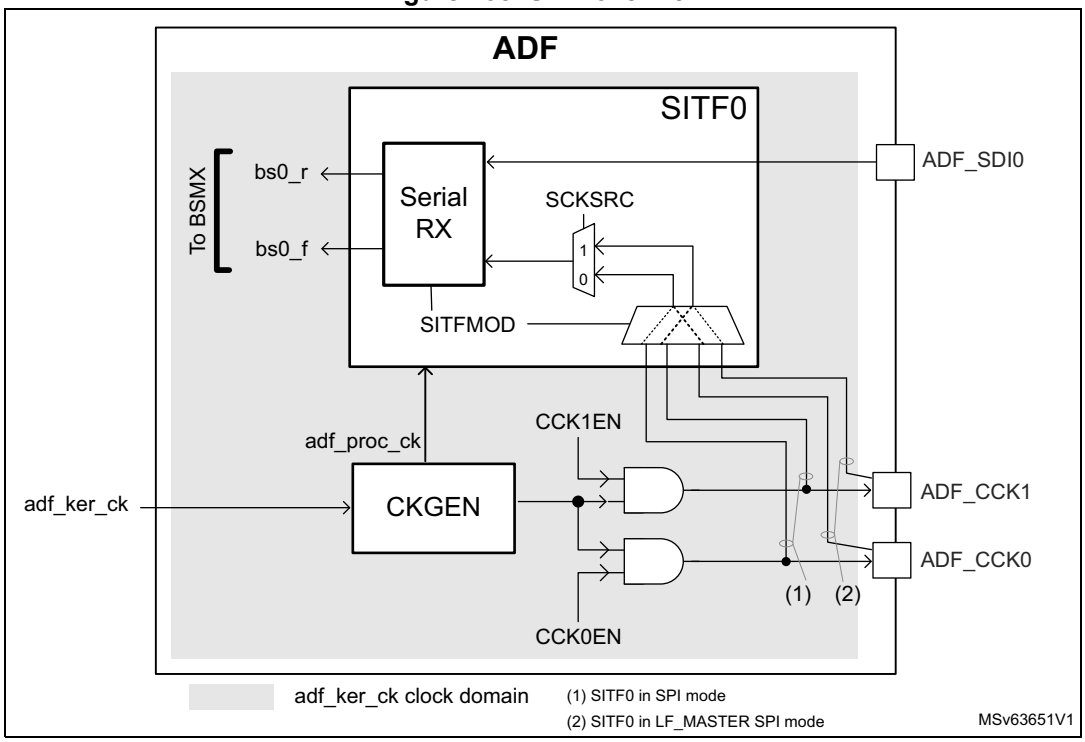
The SITF0 input interface allows the connection of the external sensor to the digital filter via the bitstream matrix (BSMX). The SITF0 can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The data from the serial interface is routed to the filter in order to perform the PDM to PCM conversion and the sound activity detection.

The serial interface is enabled by setting the SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

Note: Before enabling the *serial interface, the user must insure that the adf_proc_ck is already enabled (see Section 27.4.5: Clock generator (CKGEN) for details).*



The SITF0 is controlled via the *ADF serial interface control register 0 (ADF_SITF0CR)*.

As shown in the *Figure 208*, ADF_CCK0 or ADF_CCK1 can be selected as clock source, in order to sample the incoming bitstream:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on the ADF_CCK0 or ADF_CCK1 pin.
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source is the clock directly provided by the CCKDIV to the ADF_CCK0 or ADF_CCK1 pin.

See *Table 226* for additional information.

Figure 208. SITF overview

LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the use of an adf_proc_ck clock frequency, only two times bigger than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

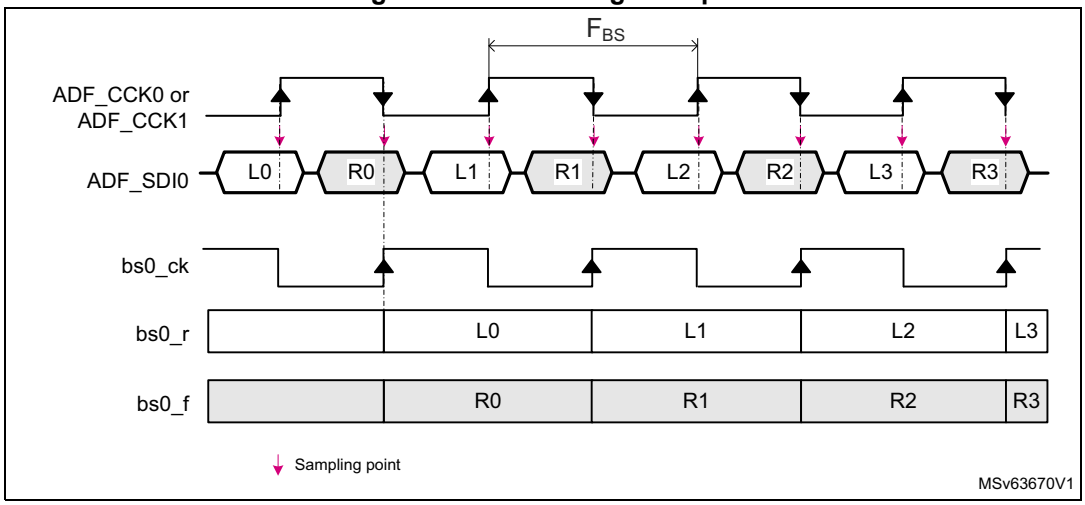
In LF_MASTER SPI mode, the ADF must provide the bitstream clock to the external sensors via ADF_CCK0 and ADF_CCK1 pins. The ADF receives the bitstream data via the serial data input ADF_SDI0.

For the SITF0, the application must select the same clock than the one provided to the external sensor (ADF_CCK0 or ADF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the adf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select ADF_CCK0 or ADF_CCK1 clock for the capture of the data received via the ADF_SDI0 pin.

The ADF can generate a clock to the sensors via ADF_CCK0 or ADF_CCK1 if needed.



For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITF0 always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bs0_f)
- bitstream received using the bitstream clock rising edge (bs0_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

Figure 209. SPI timing example

To properly synchronize/receive the data stream, the adf_proc_ck frequency must be adjusted according to the constraints listed in *Table 227*.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the SITF0. If the ADF does not detect clock transitions for a duration of STH[4:0] x $T_{adf_proc_ck}$, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the *ADF serial interface control register 0 (ADF_SITF0CR)*.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

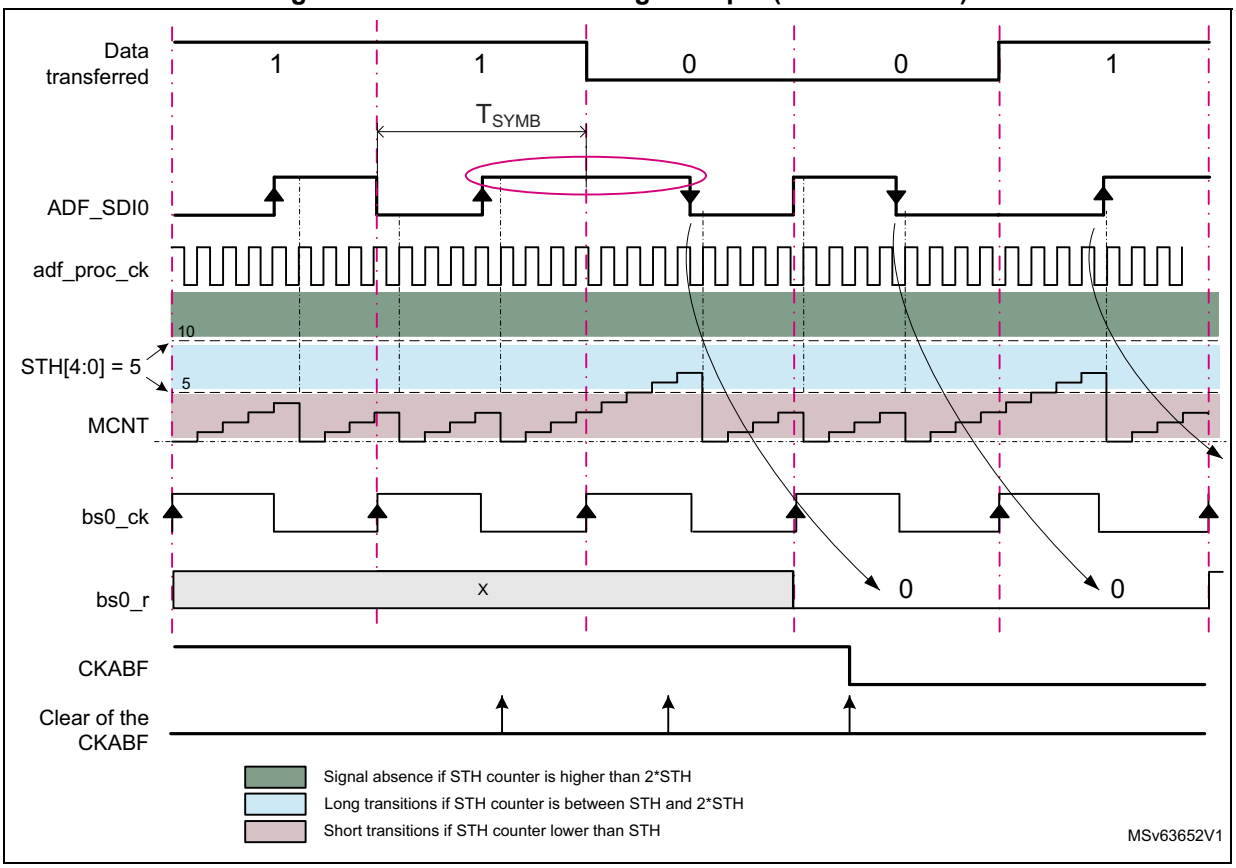
To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.

   If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.

Manchester mode



In Manchester coded format, the ADF receives data stream from the external sensor via the ADF_SDI0 pin only.

The ADF_CCK0 and ADF_CCK1 pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bs0_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

Figure 210. Manchester timing example (SITFMOD = 11)

To decode the incoming Manchester stream, the user must program STH[4:0] in the *ADF serial interface control register 0 (ADF_SITF0CR)*. The STH[4:0] bitfield is used by the SITF0 to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the ADF_SDI0 input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. *Figure 210* shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate (T_{SYMB}) must respect the following formula:

$$(STH + 1) \times T_{adf_proc_ck} < T_{SYMB} < (2 \times STH \times T_{adf_proc_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = round\left(\frac{(2 \times OVR) - 1}{3}\right)$$

where OVR represents the ratio between the adf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the adf_proc_ck clock must be adjusted according to the constraints listed in *Table 227*.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x $T_{adf_proc_ck}$, or when the SITF0 is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the ADF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the *Figure 210*) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)* by writing CKABF bit to 1. If the serial interface is not yet synchronized the hardware immediately set the CKABF flag to 1.
2. Read the CKABF flag:
   – If CKABF= 1, go back to step 1.
   – If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the ADF kernel clock frequency ($F_{adf_ker_ck}$) is 100 MHz and the received Manchester stream is at about 6 MHz (F_{SYMB}):

1. Provide a valid adf_proc_ck to the SITF0.

   The adf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).

   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, $F_{adf_proc_ck}$ = 50 MHz (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.

   OVR is given by: OVR = $F_{adf_proc_ck}$ / F_{SYMB} = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = $\text{round}\left(\frac{(2 \times 8.33) - 1}{3}\right) = 5$

   The minimum allowed frequency for the Manchester stream is then:

   1 / (2 × STH × $T_{adf_proc_ck}$) = 1 / (10 x 20 ns) = 5 MHz

   The maximum allowed frequency for the Manchester stream is then:

   1 / ((STH+1) × $T_{adf_proc_ck}$) = 1 / (6 x 20 ns) = 8.33 MHz

27.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the ADF. Refer to *Section 27.3* to check the situation for this product.

The ADF allows the connection of up to two ADCs to the filter path. For the filter, the DATSRC[1:0] bitfield in the *ADF digital filer configuration register 0 (ADF_DFLT0CICR)* allows the application to select data from the ADCs.

Warning: The ADF does not support receiving interleaved data from one of the ADCITF input.

27.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the ADF:

- AHB clock (adf_hclk) used for the register interface
- kernel clock (adf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

These clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

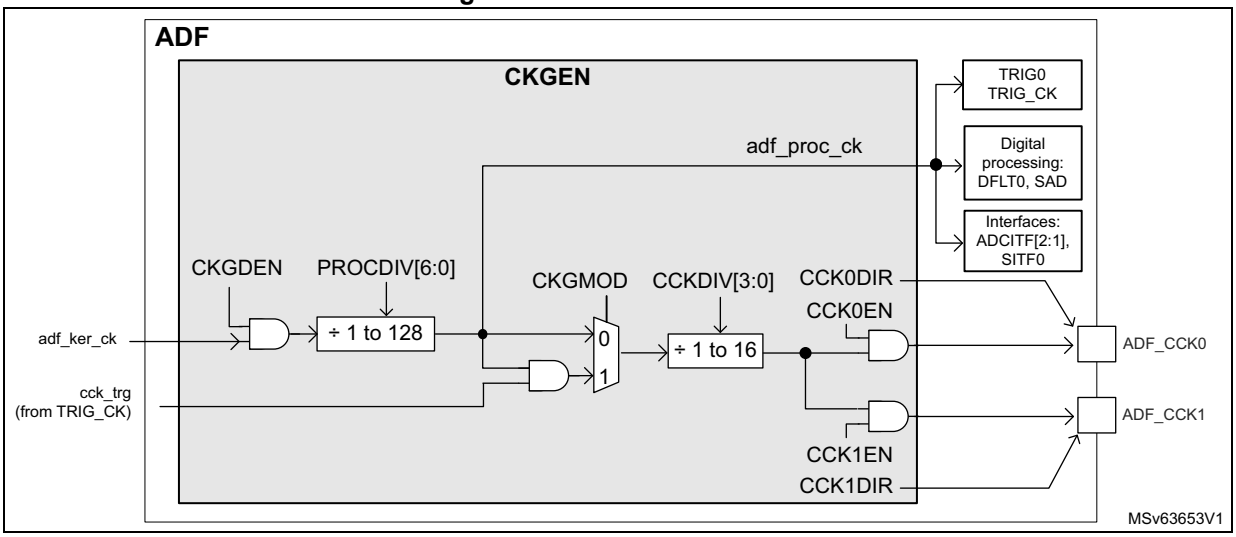
The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the ADF_CCK0 and ADF_CCK1 pins. All those clocks are generated from the adf_ker_ck.

The processing clock (adf_proc_ck) is used to run all the signal processing and to re-sample the incoming serial or parallel stream.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the ADF_CCK0 and ADF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).



The adf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All the bits and fields controlling the CKGEN are in the *ADF clock generator control register (ADF_CKGCR)*.

Figure 211. CKGEN overview

The trigger logic for CKGEN is handled by the block TRG_CK. As shown in *Figure 216*, the CCKDIV divider can be triggered on the rising or falling edge of an external trigger source. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the ADF_CCKy (y = 0,1) clock of several ADF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the ADF_CCK0 or ADF_CCK1 pin thanks to CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

Table 226. Control of the common clock generation(1)

CCKyEN	CCKyDIR	Description
0	0	The ADF_CCKy pin is in input. An external clock can be connected to the ADF_CCKy pin and used by the SITF0 in order to decode the serial stream
0	1	The ADF_CCKy pin is in output. No clock is generated. The ADF_CCKy pin is driven low.
1	1	The ADF_CCKy pin is in output. A clock is generated on the ADF_CCKy pin. The SITF0 can use this pin as clock source in order to decode the serial stream

1. The configuration with CCKyEN = 1 and CCyDIR = 0 is not shown must be avoided (no interest).

Note: The adf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITF0 or DFLT0).

CKGEN activation sequence example

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0], TRGSENS, CCK1EN and CCK0EN.
4. Set CKGDEN to 1.

When needed, at any moment, CCK[1:0]EN bitfield value can be changed without disabling the clock generator.

Clock frequency constraints

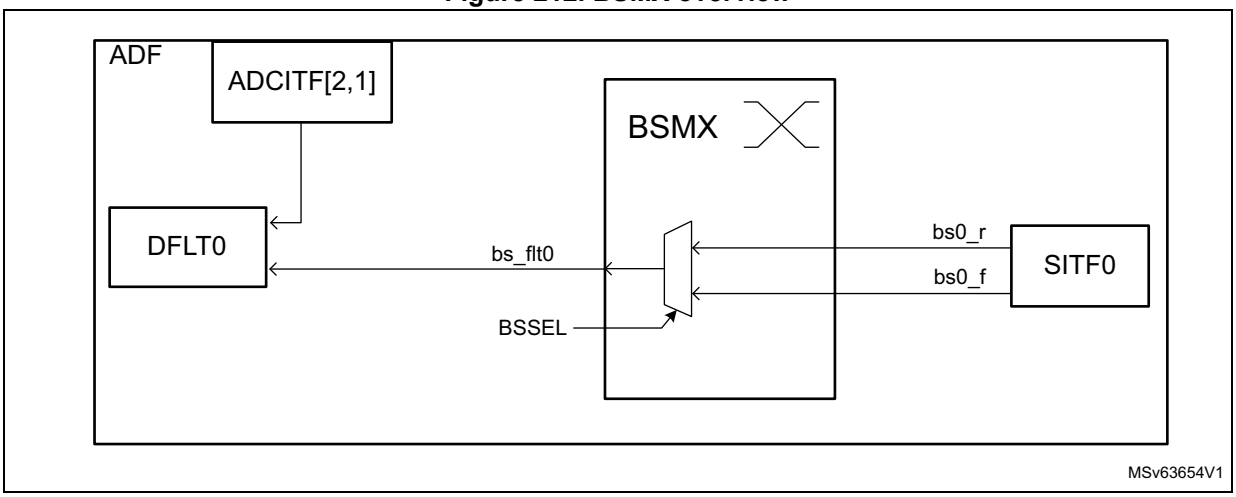
Table 227 shows the frequency constraints to receive and process properly the samples.

Note: The reshape filter (RSFLT) needs up to 24 cycles of adf_proc_ck clock to process one sample.

Table 227. Clock constraints with respect to the incoming stream(1)

SITF0 mode	ADF clock constraints	
	With RSFLT disabled	With RSFLT enabled
LF_MASTER SPI	F_{ADF_CCKy} max frequency limited to 5 MHz	
	$F_{adf_proc_ck} > 2 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 2 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$
MASTER SPI SLAVE SPI	F_{ADF_CKx} max frequency limited to 25 MHz	
	$F_{adf_proc_ck} > 4 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 4 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$
Manchester	F_{SYMB} max frequency limited to 20 MHz	
	$F_{adf_proc_ck} > 6 \times F_{SYMB}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 6 \times F_{SYMB}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$

1. F_{ADF_CCKy} represents the frequency of clock received via ADF_CCKy, or generated via ADF_CCKy. F_{SYMB} represents the frequency of the received symbol rate for Manchester mode.



27.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from the serial interface SITF0 and provides the selected stream to the digital filter DFLT0.

As shown in *Figure 207*, the SITF0 provides two bitstreams (bs0_r and bs0_f) to the BSMX.

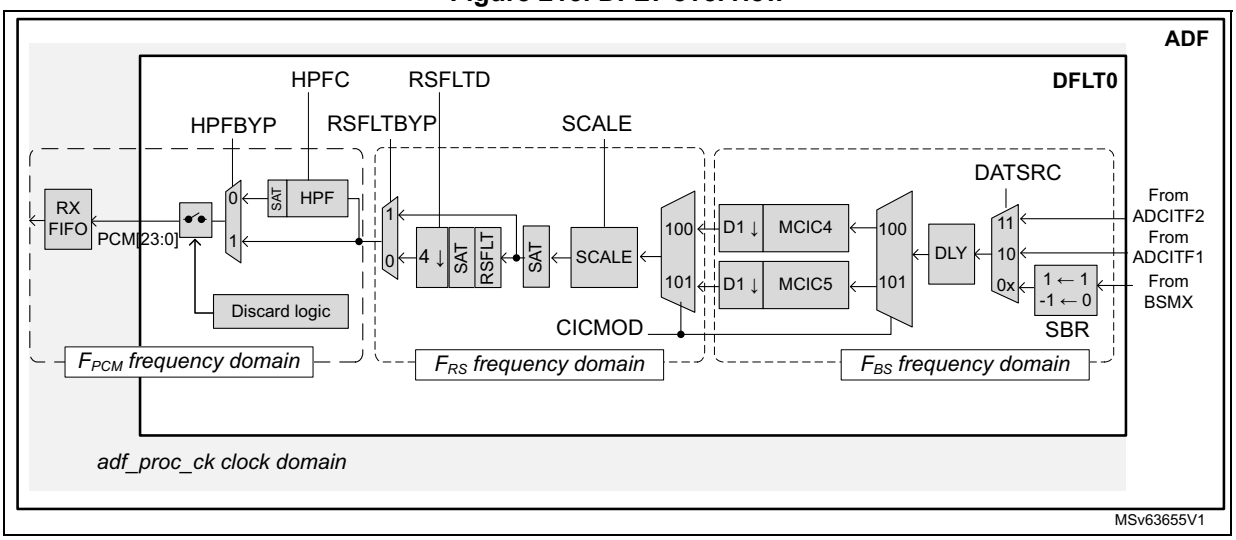
The application to select the wanted stream via the *ADF bitstream matrix control register 0 (ADF_BSMX0CR)*. This selection is intended to be static.

Figure 212. BSMX overview

BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the DFLT0 is enabled. The following steps are needed to change the value of BSMX:

1. Set DFLTEN of DFLT0 to 0.
2. Wait for BSMXACTIVE = 0.
3. Program BSSEL[4:0].
4. Set DFLTEN of DFLT0 to 1.



27.4.7 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- clock skipper delay (DLY)
- MCIC decimation filter that can be configured in $Sinc^4$ or $Sinc^5$
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- receive RXFIFO

Figure 213 shows the filter path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

Figure 213. DFLT overview

Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

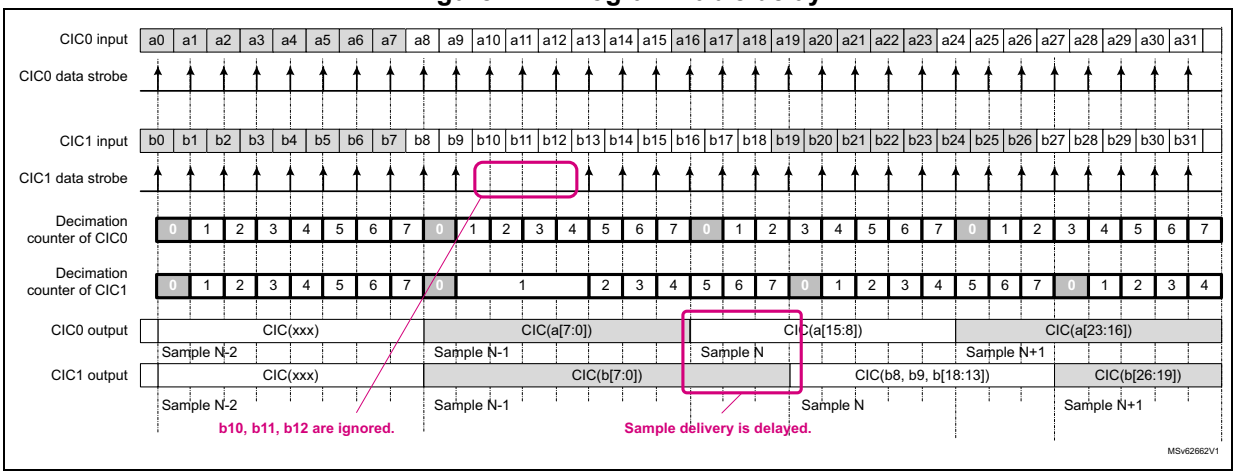
- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.



This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate must be applied to the incoming stream. This feature can be used when the ADF is synchronized with another MDF instance (if present in the product) for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is done by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

Table 214 shows an example on how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another MDF instance (if present in the product).

Figure 214. Programmable delay

The CIC of the ADF (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is built from input samples a[23:16] while the sample N+1 of CIC1 is built from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

Note: When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.

2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   – If the DFLT0 is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   – If the DFLT0 is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

   When the ADF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

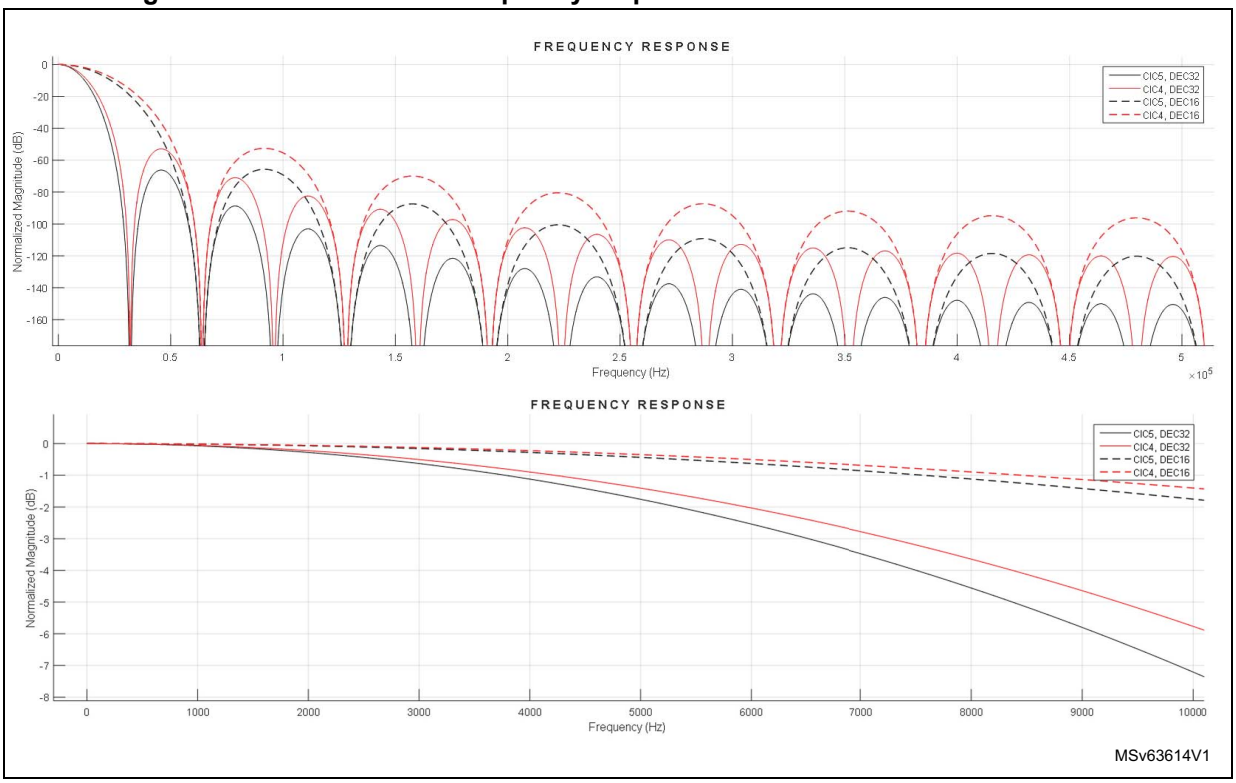
The effect of the delay performed with this mechanism is cumulative as long as the ADF is enabled. If the application performs a D1 delay followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Note: If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a $Sinc^N$ function, this is why they are often called Sinc filters.

The $Sinc^N$ digital filter embedded into the ADF can be configurable in $Sinc^4$ or $Sinc^5$, according to CICMOD:



- If CICMOD[2:0] = 4, $Sinc^4$ is selected.
- If CICMOD[2:0] = 5, $Sinc^5$ is selected.

The filters have the following transfer function:

$$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N$$

where N can be 4 or 5, and D is the decimation ratio. D is equal to MCICD+1.

Figure 215. CIC4 and CIC5 frequency response with decimation ratio = 32 or 16

CIC output data size

The size of samples delivered by the CIC (DS_{CIC}), depends on the following parameters:

- CIC order (N)
- CIC decimation ratio (D)
- data size of the input stream (DSIN)

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS_{CIC}) according to the parameters above.

$$DS_{CIC} = \left(\frac{N \times Ln(D)}{Ln(2)}\right) + DS_{IN}$$

and the CIC gain is given by this formula:

$$G_{CIC} = (D)^{N}$$

The decimation ratio can be adjusted from 2 to 512 for the CIC filter.

Table 228 gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

Note: DS_{IN} = 1 bit for a serial bitstream, but can be up to 16 bits when coming from the ADCITF.

Table 228. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITF0)		Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)	
	$Sinc^4$	$Sinc^5$	$Sinc^4$	$Sinc^5$
4	9	11	20	22
8	13	16	24	-
10	15	18	26	-
12	16	19	-	-
16	17	21	-	-
20	19	23	-	-
24	20	24	-	-
32	21	26	-	-
48	24	-	-	-
64	25	-	-	-
76	26	-	-	-

Note: For a full-scale input signal, the decimation ratio must not exceed 76 for a $Sinc^4$ and 32 for a $Sinc^5$.

The LSB parts of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-off band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

Scaling (SCALE) and saturation (SAT)

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB), and can be increased by up to 12 bits (+ 72.2 dB).

The gain is adjusted by the SCALE[5:0] bitfield in the *ADF digital filer configuration register 0 (ADF_DFLT0CICR)*.

SCALE[5:0] can be changed even if the DFLT0 is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of adf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

Table 229 shows the possible gain values.

Table 229. Possible gain values

SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)
0x20	- 48.2	0x2B	- 14.5	0x06	+ 18.1	0x11	+ 51.7
0x21	- 44.6	0x2C	- 12.0	0x07	+ 21.6	0x12	+ 54.2
0x22	- 42.1	0x2D	- 8.5	0x08	+ 24.1	0x13	+ 57.7
0x23	- 38.6	0x2E	- 6.0	0x09	+ 27.6	0x14	+ 60.2
0x24	- 36.1	0x2F	- 2.5	0x0A	+ 30.1	0x15	+ 63.7
0x25	- 32.6	0x00	0.0	0x0B	+ 33.6	0x16	+ 66.2
0x26	- 30.1	0x01	+ 3.5	0x0C	+ 36.1	0x17	+ 69.7
0x27	- 26.6	0x02	+ 6.0	0x0D	+ 39.6	0x18	+ 72.2
0x28	- 24.1	0x03	+ 9.5	0x0E	+ 42.1	-	-
0x29	- 20.6	0x04	+ 12.0	0x0F	+ 45.7	-	-
0x2A	- 18.1	0x05	+ 15.6	0x10	+ 48.2	-	-

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The ADF performs saturation operations at the following levels:

- after the SCALE block (performed by the SAT block): The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

Gain adjustment policy

To get the best ADF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full-scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

$$\frac{LN(SIN_{pp} \cdot D^N)}{LN(2)} < 26$$

where N represents the CIC order, D the decimation ratio and SIN_{pp} the maximum peak-to-peak amplitude of the input signal.

SIN_{pp}can take:

– a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF0
– A maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048), for samples coming from a 12-bit ADC

Example: a $Sinc^4$ can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

$$\frac{LN(0.7 \cdot 96^4)}{LN(2)} \sim 25.82 \text{ bits} < 26 \text{ bits}$$

2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB must be selected using this formula:

$$SCALE_{dB} < 20 \cdot \log 10\left(\frac{2^{NB}}{SIN_{pp} \cdot D^N}\right)$$

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. $SCALE_{dB}$ represents the gain value selected by SCALE[5:0].

Example: For a $Sinc^4$ with a decimation ratio of 96 and a SIN_{pp} of 0.7.

– If the RSFLT is bypassed:

$$20 \cdot \log 10\left(\frac{2^{24}}{0.7 \cdot 96^4}\right) \sim 11 \text{ dB}$$

$SCALE_{dB}$ value must be lower than - 11 dB, the closest lower value is - 12dB (SCALE[5:0] = 0x2C).

– If the RSFLT is enabled:

$$20 \cdot \log 10\left(\frac{2^{22}}{0.7 \cdot 96^4}\right) \sim 23 \text{ dB}$$

$SCALE_{dB}$ value must be lower than - 23 dB, the closest lower value is - 24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

Table 230 proposes gain values for different filter configurations, when the data comes from the SITF0, according to the MCIC order, and the MCIC decimation ratio. This table is not exhaustive and considers a full-scale input signal (see *Section 27.7.5: Total ADF gain* for details).

Table 230. Recommended maximum gain values versus CIC decimation ratios

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)		Gain settings (dB) for configuration SITF + CICx (+ HPF)	
	CIC5	CIC4	CIC5	CIC4
8	33.6	51.7	45.7	63.7
12	18.1	39.6	30.1	51.7
16	3.5	27.6	15.6	39.6
20	- 6.0	21.6	6.0	33.6
24	- 12.0	15.6	0	27.6
28	- 20.6	9.5	- 8.5	21.6
32	- 26.6	3.5	- 4.5	15.6
48	-	- 8.5	-	3.5
64	-	- 20.6	-	- 8.5

Reshaping filter (RSFLT)

In addition to the CIC, the ADF offers a reshaping IIR filter mainly dedicated to the audio application, but also usable in other applications.

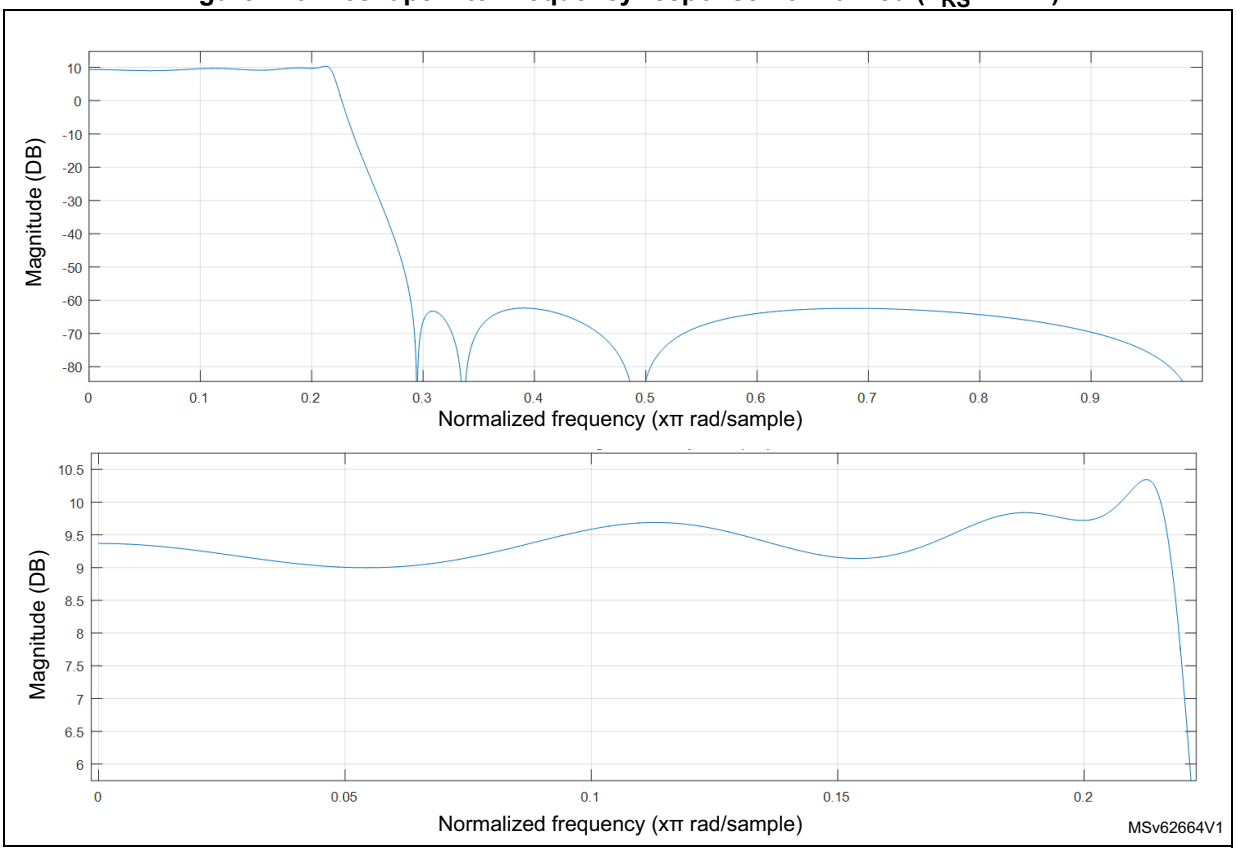
When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

The RSFLT can be bypassed by setting RSFBYP to 1 in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

Table 231 shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency (F_C) depends on the sample rates at its input (F_{RS}), and is given by the following formula:



$$F_C = 0.111 \times F_{RS}$$

Table 231. Most common microphone settings

Sample rate (kHz) at RSFLT (F_{RS})	Pass band (kHz)	D2	PCM sampling rate (kHz)
32	3.55	4	8
64	7.1	4	16
128	14.2	4	32
192	21.3	4	48

Table 216 shows the frequency response of the reshape filter.

Figure 216. Reshape filter frequency response normalized (F_{RS} / 2 = 1)

The RSFLT gain is close to 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of adf_proc_ck clock to process one sample at F_{RS}. When the RSFLT is enabled, the application must insure that the adf_proc_ck is at least 24 times faster F_{RS}.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new samples while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provides a faster adf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source that must be removed from the final data.

The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*, among the following values:

- 0.000625 x F_{PCM}
- 0.00125 x F_{PCM}
- 0.00250 x F_{PCM}
- 0.00950 x F_{PCM}

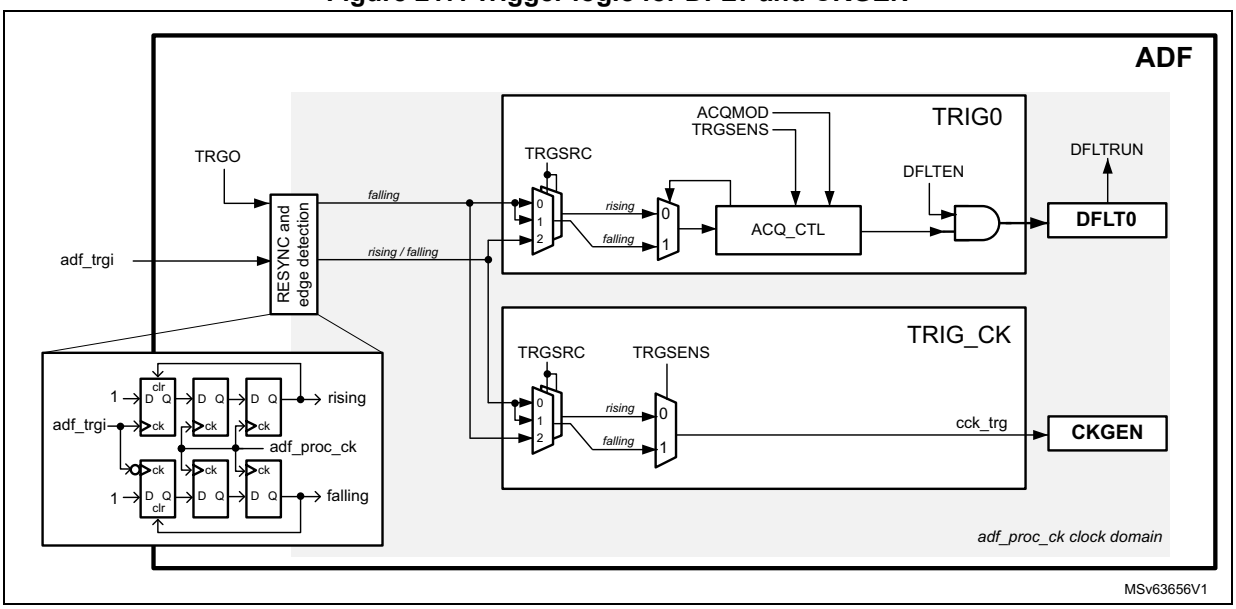
Table 232. HPF 3 dB cut-off frequency examples

HPFC	3 dB cut-off frequency for common F_{PCM} frequencies (Hz)		
	F_{PCM} = 8 kHz	F_{PCM} = 16 kHz	F_{PCM} = 48 kHz
0	5	10	30
1	10	20	60
2	20	40	120
3	76	152	456

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

27.4.8 Digital filter acquisition modes

The ADF offers the following modes to perform a data capture:



- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode

Note: To perform a data capture, the filter, the interface providing the data (SITF0 or ADCITF) and the CKGEN must be enabled. If needed, the ADF_CCK0 or ADF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This action resets the filter and flushes the RXFIFO. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filter is reset.

Table 217 shows a simplified view of the trigger logic available for each filter and for the clock generator.

Figure 217. Trigger logic for DFLT and CKGEN

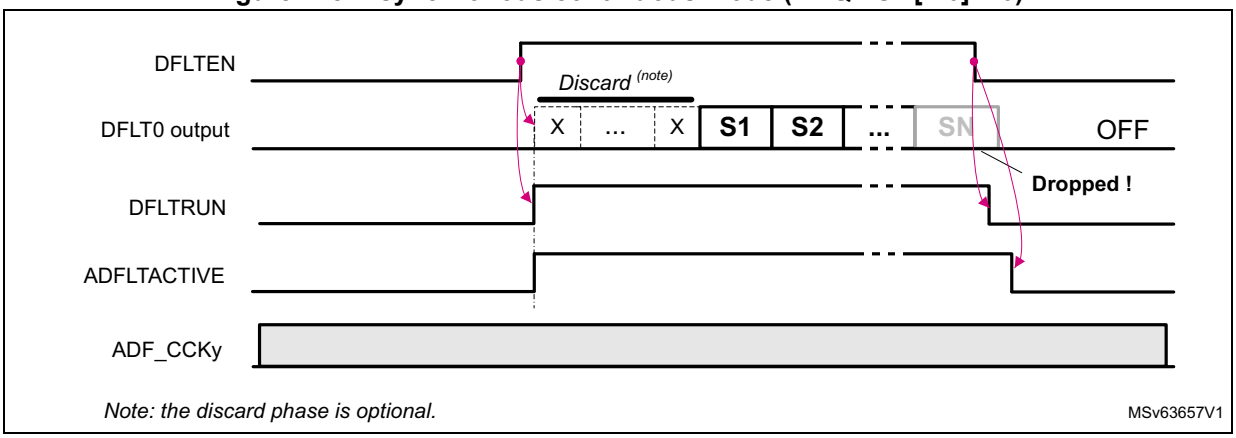
A block common to all TRIG blocks performs the rising and falling edges detection and the re-synchronization of the input trigger to the adf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the adf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select adf_trgi or TRGO bit as trigger sources. The TRGO bit is in the *ADF global control register (ADF_GCR)*.

The edge sensitivity can also be selected.

Asynchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by simply writing the DFLTEN bit to 1.



The asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN) so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 236*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the serial data interface.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the acquisition sequence starts immediately.

Figure 218 shows a simplified example of the samples generated by the DFLT0.

Figure 218. Asynchronous continuous mode (ACQMOD[2:0] = 0)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample by simply writing the DFLTEN bit to 1.

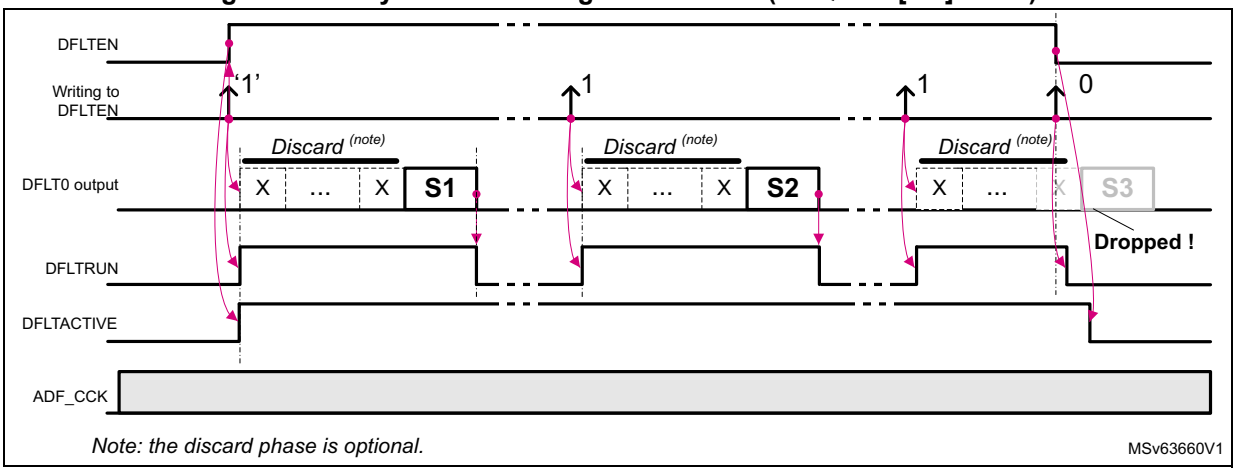
The asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 236*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.



This sequence can be repeated every time a new data must be converted.

As shown in *Figure 218*, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

Figure 219. Asynchronous single-shot mode (ACQMOD[2:0] = 001)

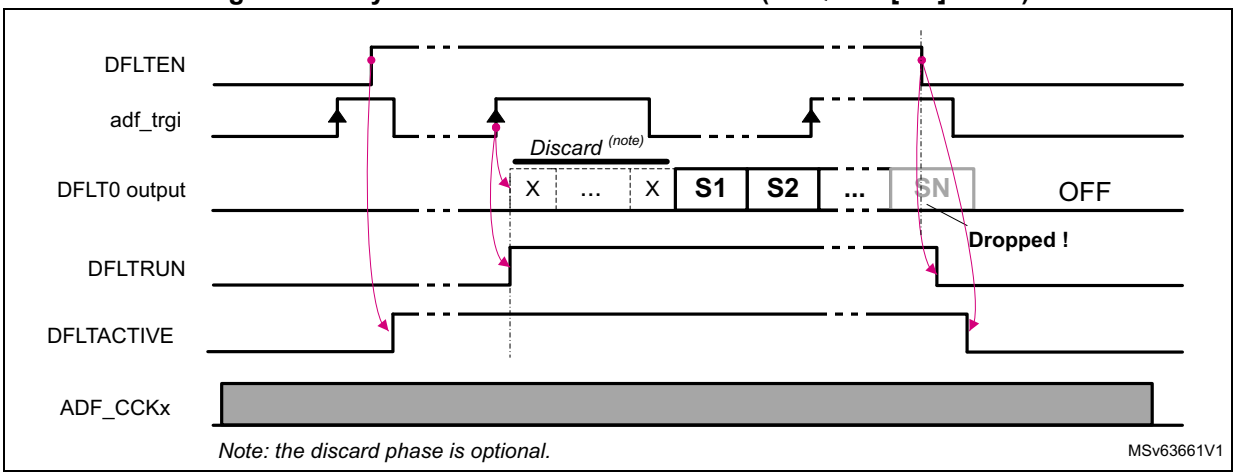
Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.



The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 236*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 010.
4. Set to 1 the bit SITFEN.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

Figure 220 shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. Then the next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

Figure 220. Synchronous continuous mode (ACQMOD[2:0] = 010)

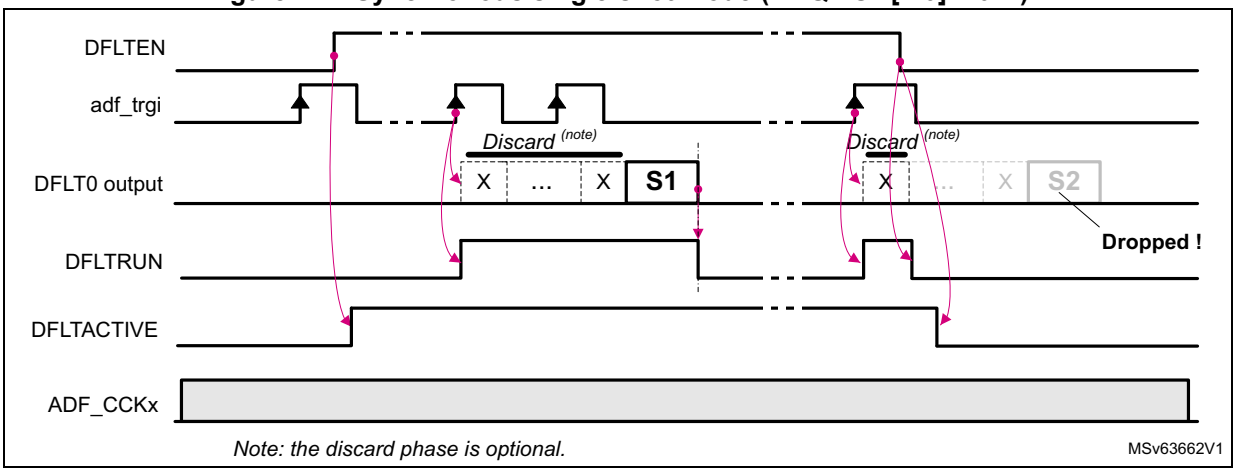
Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous single-shot acquisition mode

This mode allows the application to start a single acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.



The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 236*).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition and provides one data to the RXFIFO, then the filter is ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing, or if DFLTEN is set to 0.

Figure 221 shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every-time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 221. Synchronous single-shot mode (ACQMOD[2:0] = 011)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 220 shows a case where the DFLTEN is set to 0 while an acquisition is ongoing (the sample S2 is lost). This situation can be avoided with the following steps:

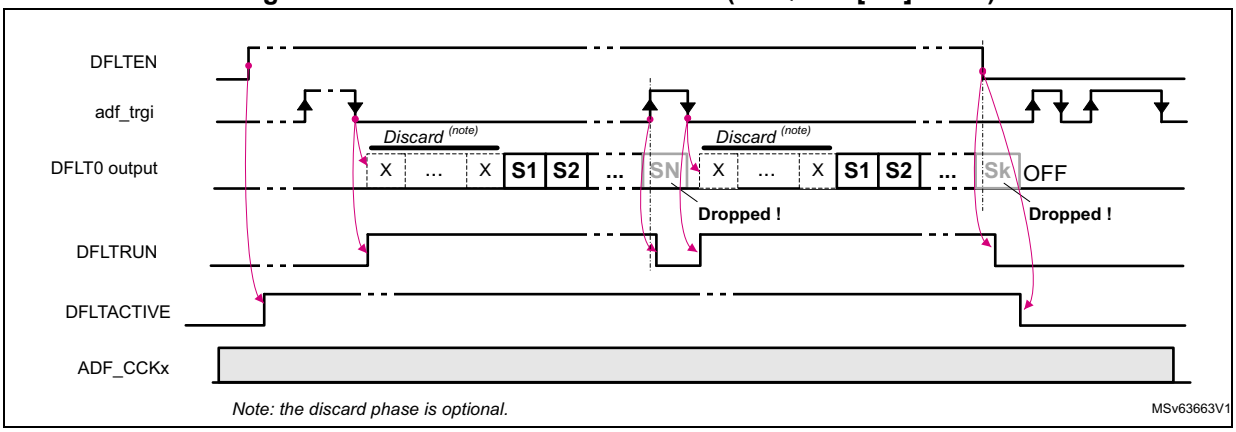
1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition controlled by consecutive edges of one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.



The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 236*).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 222 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the ADF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the ADF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the ADF waits again for a falling edge on the selected trigger input.

Figure 222. Window continuous mode (ACQMOD[2:0] = 100)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Starting several filters synchronously

If the ADF is used with MDF instances (if present in the product), it is possible to start simultaneously the acquisition of all the filters. This synchronization capability depends on the way the triggers are connected in the product. Generally, an ADF is able to trigger MDF instances, if its adf_trgo signal is connected as trigger input to those blocks (see *Section 27.4.2: ADF pins and internal signals* to check trigger capabilities).

In the following programming example, one ADF has its adf_trgo signal connected to some MDFs. To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN bits of the filters are set to 0):

On MDFs receiving the adf_trgo trigger:

1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] in order to select the adf_trgo trigger input.
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.

On the ADF generating the adf_trgo trigger:

1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK[1:0] clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. Set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. Set TRGSRC[3:0] to 0 (TRGO selected).
5. Set TRGSENS to 0 (rising edge).
6. Set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

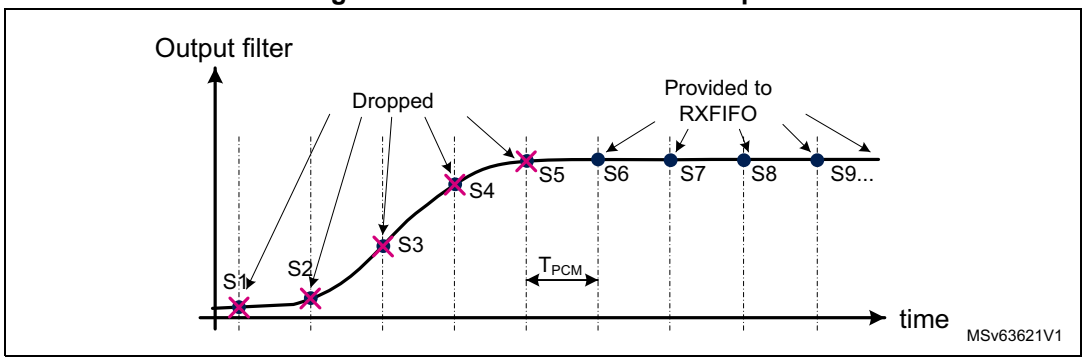
To trigger a new acquisition (in case of single-shot) the application must do the following:

1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again the bit TRGO to 1.

Discarded samples

The ADF offers the possibility to program the amount of samples to be discarded after each restart:

- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples



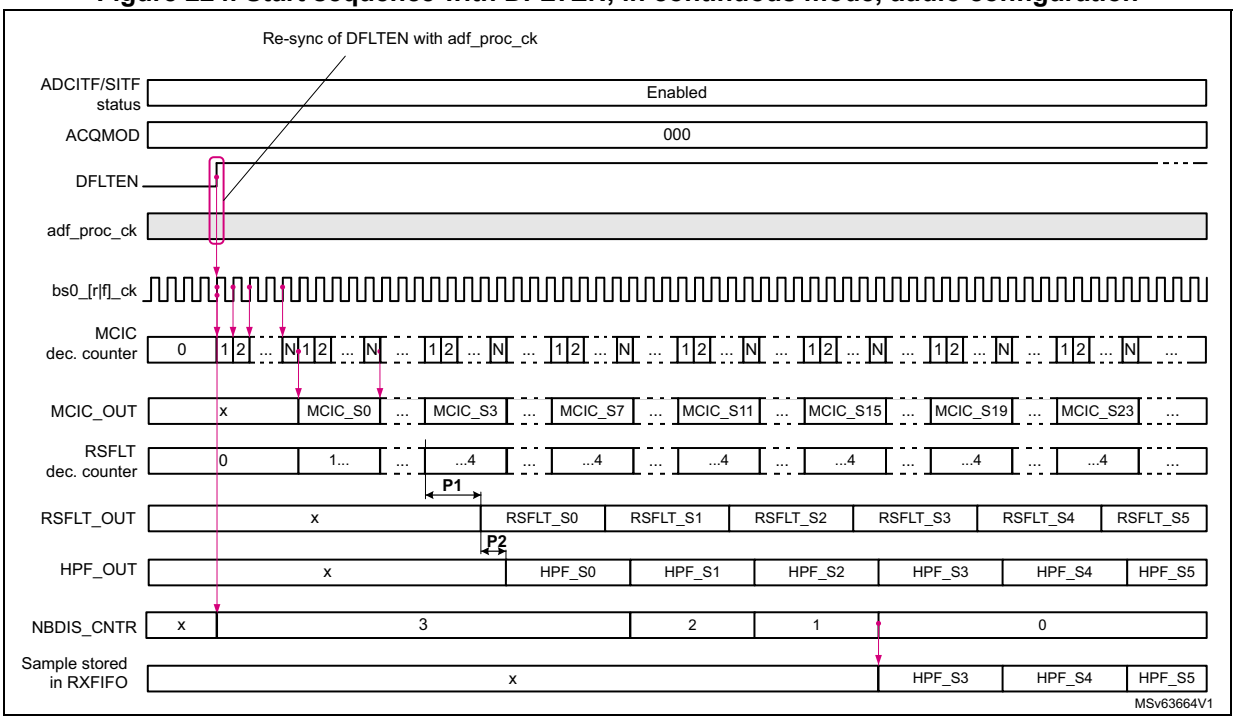
The discard function is controlled via NBDIS[7:0] as follows:

- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to *Figure 217* to *Figure 221*, and *Figure 223*.

In the example shown in *Figure 223*, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transfered to the RXFIFO is S6.

Figure 223. Discard function example



27.4.9 Start-up sequence examples

Figure 224 details a start of acquisition sequence of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLT0 is configured for audio application: MCIC, RSFLT and HPF activated.The data interface (SITF0 or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a small value to simplify the drawing.

Figure 224. Start sequence with DFLTEN, in continuous mode, audio configuration

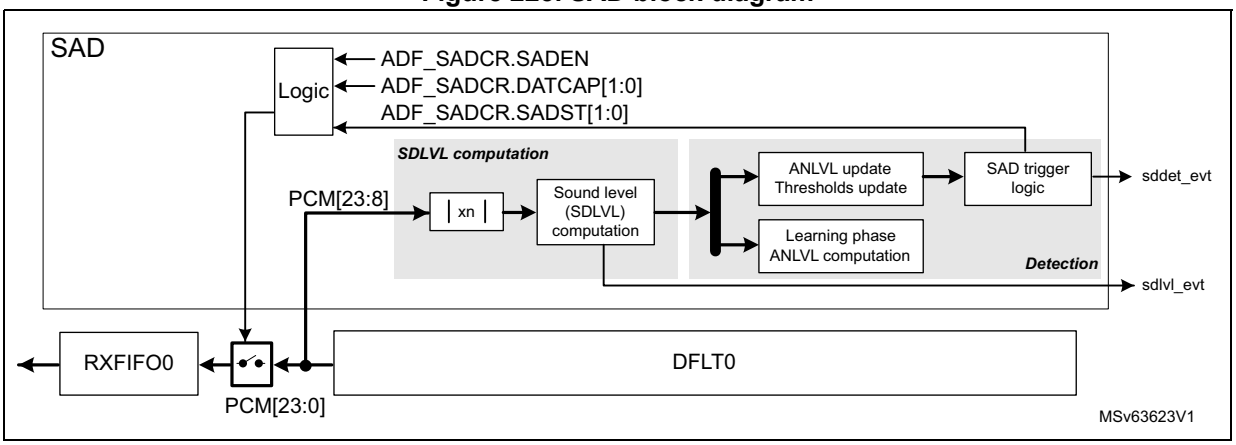
The DFLTEN bit is re-sampled into the ADF processing clock domain. When DFLTEN is detected high, the filter chain is enabled, and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reached its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC, and delivers a sample to the HPF every-time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of adf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.



27.4.10 Sound activity detection (SAD)

The SAD is based on the computation of the ambient noise level (ANLVL) and of the short-term sound level (SDLVL). The SAD offers the following ways to detect a sound:

- when the SDLVL reaches a threshold referenced to the ambient noise level
- when the SDLVL reaches a fixed threshold
- when the ANLVL reaches a fixed threshold

As shown in *Figure 225*, the SAD takes the 16 MSB samples from the DFLT0 output.

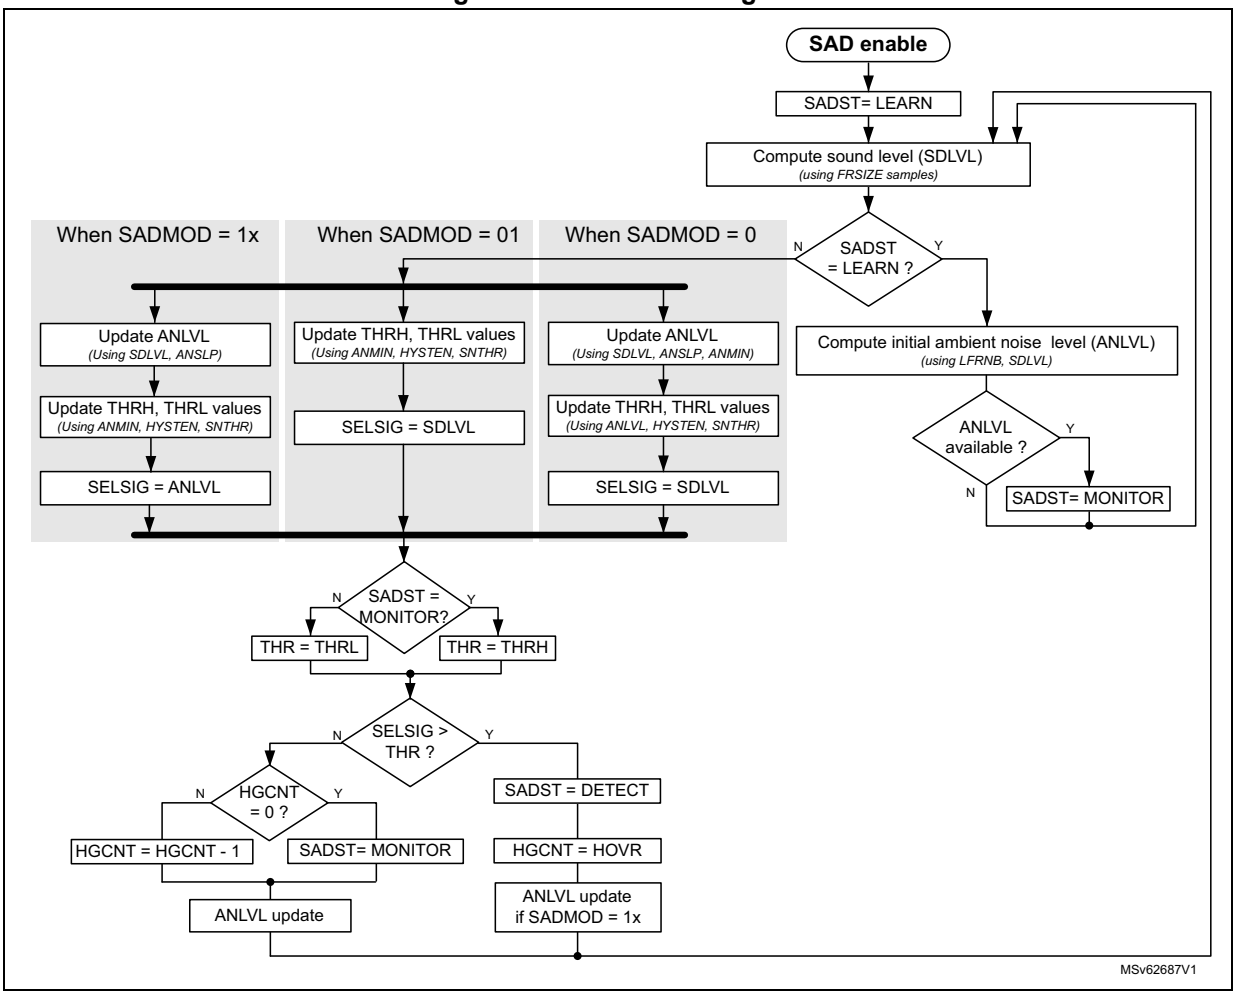
Figure 225. SAD block diagram

The SAD is highly configurable, and the application can adjust several parameters:

- SAD detection behavior (SADMOD)
- number of samples used to compute the sound level (FRSIZE)
- number of frames used to compute the ambient noise level during the learning phase (LFRNB)
- slope of the ambient noise estimator (ANSLP)
- minimum expected ambient noise level (ANMIN)
- threshold level (SNTHR)
- threshold hysteresis (HYSTEN)
- hangover window in order to filter spurious transitions between DETECT and MONITOR states (HGOVR)
- data capture mode (DATCAP)

SAD detection behavior

The SAD can use the following ways to detect a sound, selected by SADMOD[1:0]:



- When SADMOD[1:0] = 0, the SAD works like a voice-activity detection. In this mode, the SAD estimates the ambient noise level according to the computed sound level values. The threshold of the trigger is elaborated from the estimated ambient noise. Finally the current sound level is compared to this threshold. In a first approximation, the SAD triggers if the peak-to-average value of the input signal reaches a level defined by SNTHR[3:0].
- When SADMOD[1:0] = 01, the SAD compares the current sound level (SDLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode allows a fast SAD reaction as the amount of samples used to compute the sound level can be configured via FRSIZE[2:0].
- When SADMOD[1:0] = 1x, the SAD compares the estimated ambient noise level (ANLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode avoids unwanted triggers, due to peak levels, but the SAD reacts more slowly to an input signal variation. It is nevertheless possible to adjust the reaction time via FRSIZE[2:0] and ANSLP[2:0].

SAD states

As shown in *Figure 225*, the SAD works as follows:

1. When enabled (SADEN = 1), the SAD is first in LEARN state to perform a first estimation of the ambient noise level.
2. The SAD continuously computes the short-term sound level (SDLVL) using the samples provided by the DFLT0. The amount of samples used to compute the sound level is given by FRSIZE[2:0]. The samples processed by the DFLT0 can be transferred into the memory or not depending on DATCAP[1:0] value.
3. The initial ambient noise level (ANLVL) is computed using the consecutive sound level values. The application can define how much sound level values are used to perform the computation of this initial ambient noise estimation (LFRNB).
4. When the initial ambient noise level (ANLVL) is computed, the SAD switches to the MONITOR state.
5. Every time a new short-term sound level value is available, the SAD updates the ambient noise level and the thresholds according to the selected detection mode.
6. If the SAD triggers, then the following happens:
   – The SAD switches to DETECT state.
   – The sddet_evt event is asserted.
   – The adf_sad_det signal is set to high.
7. The hangover function insures that the DETECT state is maintained even if the sound level goes below the threshold level for a time given by HGOVR.

Figure 226. SAD flow diagram

Sound level computation (SDLVL)

Once enabled, the SAD computes continuously the sound level value. The sound level represents the average of the absolute value of an amount of PCM samples given by FRSIZE[2:0].

$$SDLVL = \frac{1}{N_{FRSIZE}} \times \sum_{n=1}^{N_{FRSIZE}} |PCM(n)|$$

where N_{FRSIZE} is the amount of PCM samples given by FRSIZE[2:0].

Ambient noise estimation (ANLVL)

The ambient noise level (ANLVL) is computed when SADMOD[1:0] is 00 or 10.

The ambient noise level is computed differently according to the state of the SAD as detailed below:

- ANLVL computation during the LEARN state

  Every time the SAD is enabled, a learning phase is initiated in order to estimate a first value of the ambient noise level. During this phase, the SAD cannot trigger.

  During the LEARN phase, the ambient noise level is computed as follows:

$$ANLVL = \frac{1}{N_{LFRNB}} \times \sum_{n=1}^{N_{LFRNB}} |SDLVL(n)|$$

  where N_{LFRNB} is the amount of frames given by LFRNB[2:0] bitfield.

- ANLVL computation during the MONITOR or DETECT state

  When the learning phase is completed, the SAD updates the ambient noise level in the following way:

  – The SAD computes the new possible values for the ambient noise level:

    ANLVL_UP = ANLVL * (1+2^(ANSLP-12))

    ANLVL_DN = ANLVL * (1-2^(ANSLP-10))

  – The ANLVL takes the ANLVL_DN value if the current sound level is lower than ANLVL_DN, otherwise ANLVL takes the value of ANLVL_UP.

    The ANLVL is not updated if the current sound level is higher than the threshold level, except if SADMOD[1:0] = 10.

  – When SADMOD[1:0] = 0, if the new ANLVL value is lower than ANMIN[12:0], ANLVL is replaced by ANMIN.

  The slope of the noise estimator can be adjusted to optimize the detection of the wanted signal. This slope is adjusted via ANSLP[2:0] in the *ADF SAD configuration register (ADF_SADCFGR)*.

Table 233 shows the allowed values according to the frame size and the sampling rate of the data observed by the SAD. The recommended values when the SADMOD[1:0] = 0 are the ones into the gray shaded cells.

Table 233. ANSLP values versus FRSIZE and sampling rates

FRSIZE	ANSLP values for Fs = 8 kHz			ANSLP values for Fs = 16 kHz		
	Slow(1)	typical(2)	Fast(3)	Slow(1)	typical(2)	Fast(3)
0 (8 samples)	0	1	2	-	0	1
1 (16 samples)	1	2	3	0	1	2
2 (32 samples)	2	3	4	1	2	3
3 (64 samples)	3	4	5	2	3	4
4 (128 samples)	4	5	6	3	4	5
5 (256 samples)	5	6	7	4	5	6
6 (512 samples)	6	7	-	5	6	7

1. The slow slope is equal to - 8.5 dB/s for the negative slope and + 2.1 dB/s for the positive slope.
2. The typical slope is equal to - 17.1 dB/s for the negative slope and + 4.2 dB/s for the positive slope.
3. The fast slope is equal to - 34.2 dB/s for the negative slope and + 8.5 dB/s for the positive slope.

The slopes can also be computed using the following formulas:

$$SLC_{UP} = 20 \times \frac{F_s}{F_{SIZE}} \times \log 10(1 + 2^{(ANSLP - 12)})$$

$$SLC_{DN} = 20 \times \frac{F_s}{F_{SIZE}} \times \log 10(1 - 2^{(ANSLP - 10)})$$

where F_S is the sampling rate of the stream observed by the SAD and F_{SIZE} is the frame size defined by FRSIZE[2:0].

Threshold computation

The way the threshold value is computed depends on SADMOD[1:0]:

- If SADMOD[1:0] = 0, THRH is obtained by multiplying the current ANLVL value with the gain defined in SNTHR[3:0].

  $$THR_H = ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}$$

  This threshold value is then compared to the current sound level (SDLVL).
- If SADMOD[1:0] = 01, THRH is obtained by multiplying the current ANMIN[12:0] with the gain defined by SNTHR[3:0].

  $$THR_H = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}$$

  This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 1x, THRH is obtained by multiplying the current ANMIN[12:0] by 4.

$$THR_H = ANMIN \times 4$$

This threshold value is then compared to:

$$ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}$$

The hysteresis mode can be enabled to reduce the spurious transitions between MONITOR and DETECT states. In hysteresis mode (HYSTEN = 1), the following threshold values are used:

- THRH when the SAD is in MONITOR state.
- THRL when the SAD is in DETECT state.

Table 234 shows the thresholds values according to SNTHR.

Table 234. Threshold values according SNTHR(1)

SNTHR[3:0]	THR_H		THR_L		Comments
0	LVL + 3.5 dB	LVL x 1.5	LVL + 3.5 dB	LVL x 1.5	No hysteresis
1	LVL + 6.0 dB	LVL x 2	LVL + 3.5 dB	LVL x 1.5	Hysteresis of 2.5 dB
2	LVL + 9.5 dB	LVL x 3	LVL + 6.0 dB	LVL x 2	Hysteresis of 3.5 dB
3	LVL + 12.0 dB	LVL x 4	LVL + 9.5 dB	LVL x 3	Hysteresis of 2.5 dB
4	LVL + 15.6 dB	LVL x 6	LVL + 12.0 dB	LVL x 4	Hysteresis of 3.5 dB
5	LVL + 18.1 dB	LVL x 8	LVL + 15.6 dB	LVL x 6	Hysteresis of 2.5 dB
6	LVL + 21.6 dB	LVL x 12	LVL + 18.1 dB	LVL x 8	Hysteresis of 3.5 dB
7	LVL + 24.1 dB	LVL x 16	LVL + 21.6 dB	LVL x 12	Hysteresis of 2.5 dB
8	LVL + 27.6 dB	LVL x 24	LVL + 24.1dB	LVL x 16	Hysteresis of 3.5 dB
9	LVL + 30.1 dB	LVL x 32	LVL + 27.6dB	LVL x 24	Hysteresis of 2.5 dB

1. LVL must be replaced by ANLVL when SADMOD[1:0] = 0 and by ANMIN for other SADMOD[1:0] values.

When the hysteresis function is disabled, the SAD always use THRH.

Note: The hysteresis mode must not be used when SADMOD[1:0] = 1x.

Trigger logic

The signal compared to this threshold depends also on SADMOD[1:0].

The trigger condition is reached when the selected signal (SELSIG) is bigger than the threshold level.

If the trigger condition is met, the following happens:

- The SAD switches to DETECT state.
- The SAD refreshes the hangover counter with HGOVR.
- The sddet_evt event is asserted if the SAD transits from MONITOR to DETECT.

- The adf_sad_det signal is set to high.

The SAD remains in DETECT state as long as the trigger condition is met or the hangover down-counter is different from 0.

The sddet_evt event indicates when the SAD enters and/or exits the DETECT state. This event is used to generate an interrupt when a sound is detected or when a sound is no longer detected:

- When DETCFG = 0, the application receives an event only when the SAD enters the DETECT state.
- When DETCFG = 1, the application receives an event when the SAD enters or exits the DETECT state.

The adf_sad_det signal remains high as long as the SAD is in DETECT state.

The SAD also provides a flag indicating that a new sound level value is available (SDLVLF). The last computed sound level (SDLVL[14:0]) is available in the *ADF SAD sound level register (ADF_SADSDLVR)*, and the last computed ambient noise level (ANLVL[14:0]), in the *ADF SAD ambient noise level register (ADF_SADANLVR)*.

Note: The SAD can work even when the AHB clock is not present. In that case, the SAD does not update SDLVL[14:0] and ANLVL[14:0].

To get the latest valid SDLVL[14:0] and ANLVL[14:0] values, the application must read the ADF_SADSDLVR, and ADF_SADANLVR registers, when the SDLVLF flag goes high. This can be done in the following ways:

- by polling the SDLVLF flag:
  a) Clear the SDLVLF flag by writing SDLVLF to 1.
  b) Wait for SDLVLF = 1, by reading ADF_DFLTxISR.
  c) Read ADF_SADSDLVR and ADF_SADANLVR.
  d) Clear SDLVLF by writing it to 1.
  e) Go to step 2 if other values must to be read.
- by generating an interrupt:
  a) Read ADF_DFLTxISR.
  b) If SDLVLF = 1, read ADF_SADSDLVR and ADF_SADANLVR, and clear SDLVLF by writing it to 1.
  c) Handle other status flags and exit from ISR.

Sample transfer to memory

The SAD offers the following options to control the samples transfer from DFLT0 to the system memory:

- If DATCAP[1:0] = 1x, the samples are transferred into the system memory as soon as DFLT0 and SAD are enabled. The transfer does not depend on the SAD state.
- If DATCAP[1:0] = 01, the samples are transferred into the system memory when the SAD detects a sound (when the SAD is in DETECT state), assuming that DFLT0 and SAD are enabled.
- If DATCAP[1:0] = 0, the samples are not transferred into the memory. This mode can be used if the application only wants to observe but does not need samples for other processing.

Note: DATCAP[1:0] is taken into account only when the SADEN = 1. For example, if the SAD configuration is DATCAP[1:0] = 0, SADEN = DFLTEN = 1, and if the application sets now SADEN to 0, the samples provided by the DFLT0 are transferred to the RXFIFO.

Programming recommendations

To make the SAD function working properly, the ADF must be programmed as follows:

1. Provide the proper kernel clock (adf_ker_ck) to the ADF.
2. Configure the CKGEN and enable it.
3. Configure the SITF and enable it (note that microphones have a settling time of several milliseconds).
4. Configure the DFLT0. A typical setting is the following:
   - CIC5 with a decimation ratio of 12, 16 or 24
   - RSFLT with a decimation ratio of 4
   - HPF with HPFC = 2 or 3

   For a very-low power implementation, the RSFLT can be bypassed.
5. Set SADEN to 0.
6. Wait for SADACTIVE = 0. If SADEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
7. Configure the SAD as follows:
   - Set DATCAP[1:0] to 0, if the application does not want to store the samples into the system memory.
   - Set DATCAP[1:0] to 01, if the application wants to store the samples into the system memory only when the SAD detects a sound.
   - Set DATCAP[1:0] to 11, if the application wants to store the samples into the system memory continuously.
8. Configure the DMA (optional).
9. Enable the SAD.
10. Enable the DFLT0.

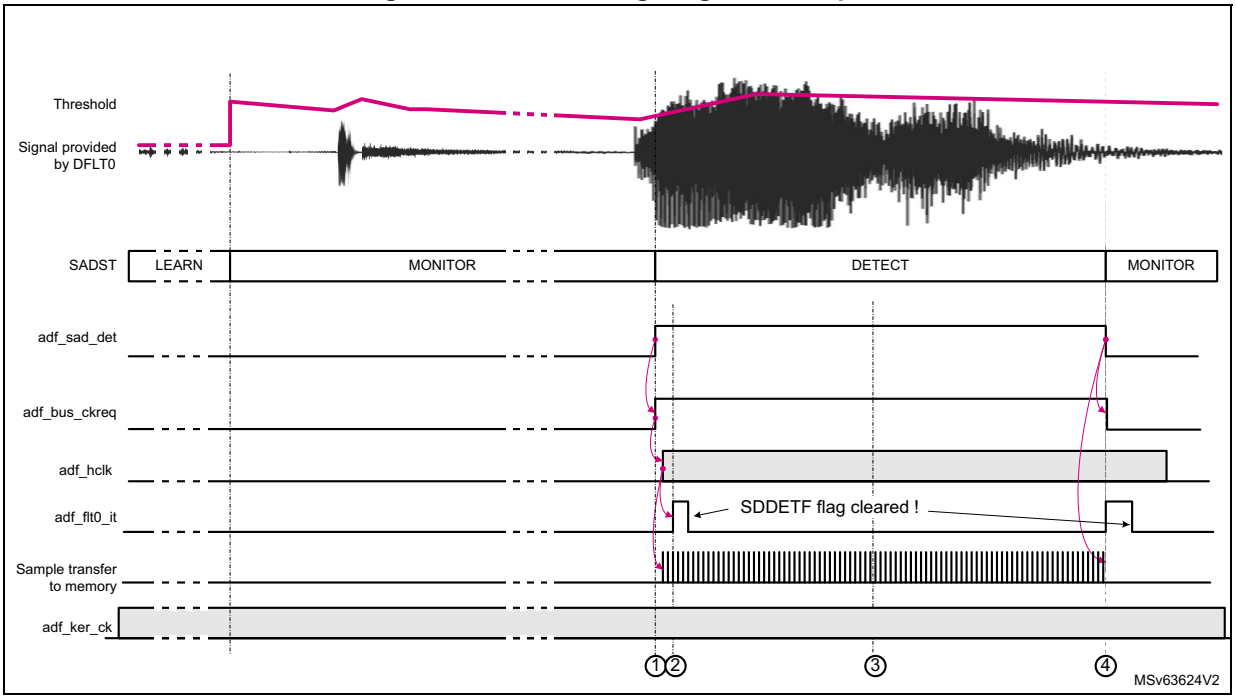


Figure 226 shows a simplified timing diagram when the SAD works with DATCAP[1:0] = 01.

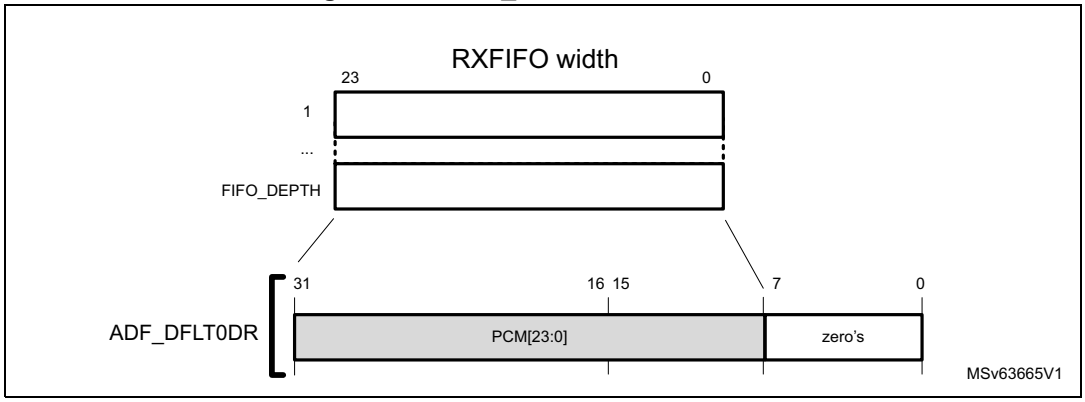
Thanks to the kernel clock (adf_ker_ck), the SAD continuously monitors the audio signal provided by the DFLT0. The threshold is also continuously updated according to the ambient noise level estimation.

- When the SAD detects a sound higher than the programmed threshold (1), the ADF requests the bus clock (adf_bus_ckreq asserted).
- When the bus clock is available (see 2 in *Figure 226*) then:
  - The data transfer to the memory is triggered.
  - The event interrupt (adf_evt_it) can be generated.
- In this example, the event interrupt (adf_evt_it) is used to wake up the application. The interrupt line is released by clearing SDDETF by writing 1 to it.
- As long as the SAD remains in DETECT state, the application waits to get enough samples and calls, for example the keyword recognition algorithm (see 3 in *Figure 226*).
- In the case shown in *Figure 227*, the SAD state (SADST) goes back to MONITOR before the keyword is recognized. If DETCFG is set to 1, an event signals when the SAD goes back to MONITOR state. The SAD stops the transfer of samples into the

memory and the application can clean up the receive buffer for the next detection (see 4 in *Figure 226*).

Figure 227. SAD timing diagram example



27.4.11 Data transfer to memory

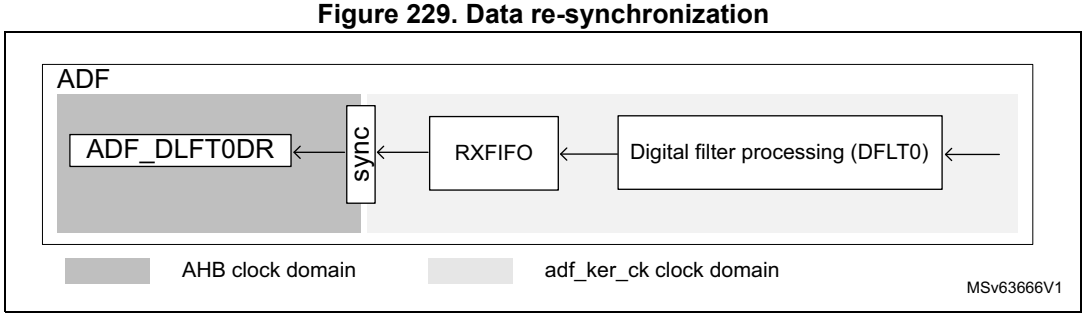
Data format

The samples processed by DFLT0 are stored into a RXFIFO. The application can read the samples stored into these FIFOs via the *ADF digital filter data register 0 (ADF_DFLT0DR)*. The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The ADF provides 24-bit left-aligned data. Performing a 16-bit access to ADF_DFLT0DR allows the application to get the 16 most significant bits. Performing a 32-bit access to ADF_DFLT0DR allows the application to get a 24-bit data size.

Figure 228. ADF_DFLTxDR data format

Data re-synchronization



The samples stored into the RXFIFO can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFO is located into the adf_ker_ck clock domain, while ADF_DFLT0DR *is located into the adf_hclk (AHB) clock domain.*

When the AHB clock is available, if ADF_DFLT0DR is empty and if a sample is available into the RXFIFO, this sample is transferred into ADF_DFLT0DR.

The sample transfer from the RXFIFO to ADF_DFLT0DR takes two periods of the AHB clock (adf_hclk) and two periods of the adf_ker_ck clock. The ADF inserts automatically wait-states if the application performs a read operation of ADF_DFLT0DR while the transfer of the new sample from the RXFIFO to ADF_DFLT0DR is not yet completed.

Figure 229. Data re-synchronization

Data transfer

The content of the RXFIFO can be transfered to the memory either by using a DMA channel or interrupt services.

Both single and burst, DMA transfers are supported by the ADF, but the application has to care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

Note: The burst mode is not available in all products (see the DMA section to check if the product supports it).

In addition, the application can select the RXFIFO threshold (FTH bit) in order to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth/2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the RXFIFO is not empty.

The DMA mode of the RXFIFO is enabled via the DMAEN bit in ADF_DFLT0DR.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as ADF_DFLT0DR is read.
- If FTH = 1, as soon as the RXFIFO reaches the threshold level and a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as one data is read. FTHF is set again if the threshold condition is

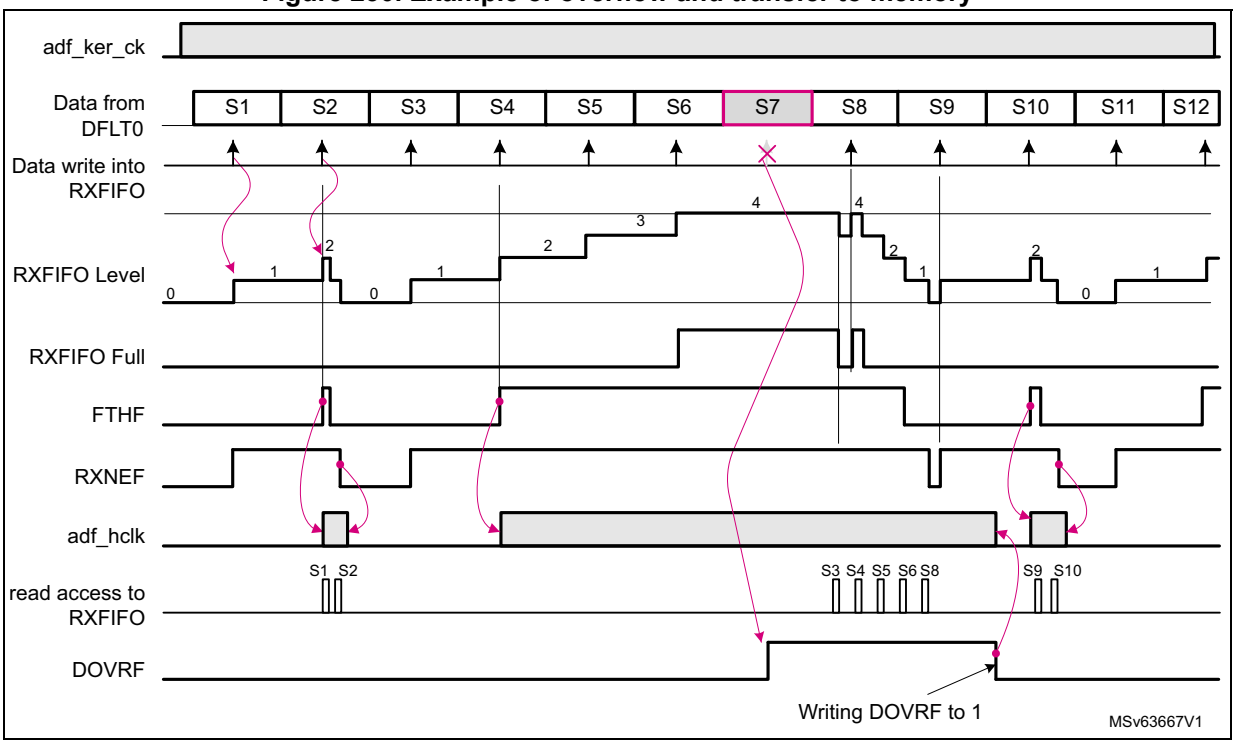
met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE/2 data.

RXFIFO overrun

A RXFIFO overrun condition is detected when the RXFIFO is full, and a new sample from the DFLT0 must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 230 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.



The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO, and the ADF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the adf_hclk line, the gray boxes indicate that the ADF requested the AHB clock. *Figure 230* shows the AHB clock available only when the ADF requests it. In real applications, the AHB clock may also be present if the ADF does not request it.

Figure 230. Example of overflow and transfer to memory

27.4.12 Autonomous mode

The ADF can work even if the AHB bus clock is not available (Stop modes). The ADF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the ADF receives a kernel clock if the following conditions are met:

- The ADF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the ADF receives the AHB clock if the following conditions are met:

- The ADF autonomous mode is enabled in the RCC.
- The ADF requests the AHB clock in the following situations:
  - when the ADF must transfer data into memory via the DMA

    The data is directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the ADF needs to generate an interrupt

    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated.The AHB clock request is maintained as long as an enabled interrupt flag is still active.

27.4.13 Register protection

The ADF embeds some hardware protection to prevent invalid situations.
Table 235 shows the list of write-protected and unprotected fields.

Table 235. Register protection summary

Registers	Unprotected fields	Write-protected fields	Write-protection condition
ADF global control register (ADF_GCR)	TRGO	-	DFLTACTIVE0 = 1
ADF clock generator control register (ADF_CKGCR)	CKGDEN CCK0EN CCK1EN	PROCDIV[6:0], CCKDIV[3:0], CKGMOD, TRGSRC[3:0], TRGSENS, CCK[1:0]DIR	CKGACTIVE = 1
ADF serial interface control register 0 (ADF_SITF0CR)	SITFEN	STH[4:0], SITFMOD[1:0], SCKSRC[1:0]	SITFACTIVEx = 1
ADF bitstream matrix control register 0 (ADF_BSMX0CR)	-	BSSEL[4:0]	DFLTACTIVEx = 1
ADF digital filter control register 0 (ADF_DFLT0CR)	DFLTEN	NBDIS[7:0], TRGSRC[3:0], TRGSENS, FTH, DMAEN, SNPSFMT, ACQMOD[2:0]	DFLTACTIVEx = 1
ADF digital filer configuration register 0 (ADF_DFLT0CICR)	SCALE[5:0]	MCICD[8:0], CICMOD[2:0], DATSRC[1:0]	
ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)	-	All fields	
ADF delay control register 0 (ADF_DLY0CR)	-	SKPDLY[6:0]	SKPBF = 1

Table 235. Register protection summary (continued)

Registers	Unprotected fields	Write-protected fields	Write-protection condition
ADF DFLT0 interrupt enable register (ADF_DFLT0IER)	All fields	-	-
ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)	All fields	-	-
ADF SAD control register (ADF_SADCR)	SADEN	FRSIZE[2:0], DETCFG, SADMOD[1:0], HYSTEN, DATCAP[1:0]	SADACTIVE = 1
ADF SAD configuration register (ADF_SADCFGR)	-	ANMIN[12:0], SNTHR[3:0], HGOVR[3:0], LFRNB[2:0], ANSLP[2:0]	SADACTIVE = 1

All the ADF processing is performed in the adf_proc_ck clock domain. For that reason, enabling or disabling an ADF sub-block may take some time due to the re-synchronization between the AHB clock domain and the adf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for details.

27.5 ADF low-power modes

Table 236. Effect of low-power modes on ADF

Mode	Description
Sleep	No effect. ADF interrupts cause the device to exit the Sleep mode.
Stop(1)	The ADF registers content is kept. Thanks to the kernel clock request feature, if the ADF is clocked by an internal oscillator available in Stop mode, the ADF remains active. The interrupts cause the device to exit Stop mode.
Standby	The ADF is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 27.3: ADF implementation* for details about Stop modes supported by the ADF.

27.6 ADF interrupts

To increase the CPU performance, the ADF offers an interrupt line (adf_flt0_it), sensitive to several events.

Note: The status flags are available even if the corresponding interrupt enable flag is not enabled.

The interrupt interface is controlled via the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and the *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

Figure 231. ADF interrupt interface

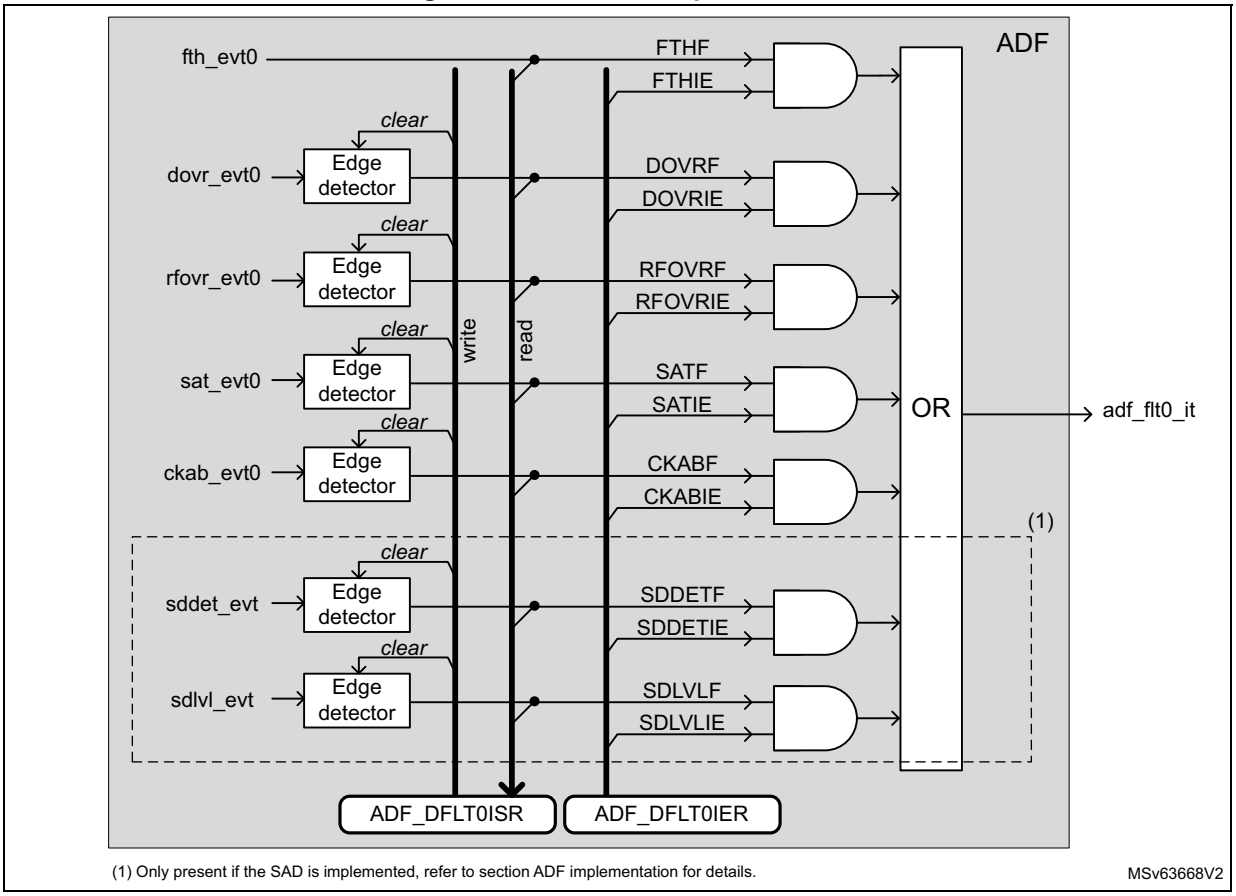


Table 237 shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

Table 237. ADF interrupt requests

Interrupt vector	Interrupt event	Event flag	Event/interrupt clearing method	Exit Sleep mode	Exit Stop modes(1)	Exit Standby mode
ADF_FLT0(2)	RXFIFO threshold reached	FTHF	Read ADF_DFLT0DR until RXFIFO level is lower than the threshold.	Yes	Yes	No
	RXFIFO overrun	DOVRF	Write DOVRF to 1.			
	RSFLT overrun	RFOVRF	Write RFOVRF to 1.			
	Saturation detection	SATF	Write SATF to 1.			
	Channel clock absence detection	CKABF	Write CKABF to 1.			
	SAD: sound detected	SDDETF	Write SDDETF to 1.			
	SAD: sound level value available	SDLVLF	Write SDLVLF to 1.			

1. Refer to *Section 27.3: ADF implementation* for details.
2. ADF_FLT0 vector corresponds to the assertion of adf_flt0_it signal.

27.7 ADF application information

27.7.1 ADF configuration examples for audio capture

Table 238 gives some examples of the ADF settings for the digital microphones, focusing on 16 and 48 kHz output data rate.

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (adf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple, and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

Table 238. Examples of ADF settings for microphone capture

Configuration	adf_ker_ck (MHz)	PROCDIV + 1	CCKDIV + 1	CIC order (1)	MCICD + 1	SCALE	RSFLTBYP	RSFLTD	HPFBYP	-	adf_proc_ck (MHz)	Total dec. ratio	F_{RS} (kHz)	F_{ADF_CCKx} (MHz)	F_{PCM} (kHz)
#1	1.024	1	2	4	64	0x2D (- 8.5 dB)	1	x	x	=>	1.024	64	-	0.512	8
#2		1	2	5	32	0x2B (- 14.5 dB)						32	-		16
#3		1	2	5	16	0x01 (+ 3.5 dB)	0	0				64	32		8
#4	2.048	1	2	5	16	0x01 (+ 3.5 dB)	0	0			2.048	64	64	1.024	16
#5	3.072	1	6	5	8	0x0B (+ 33.6 dB)	0	0			3.072	32	32	0.512	8
#6		2	2	5	12	0x06 (+ 18.1 dB)						48	64	0.768	16
#7		1	2	5	24	0x2C (- 12 dB)						96		1.536	
#8	4.096	1	2	5	32	0x27 (- 26.6 dB)	0	0			4.096	128	64	2.048	16
#9	6.144	3	2	5	16	0x02 (+ 6.0 dB)	0	0			2.048	64	64	1.024	16
#10		2	2	5	24	0x2C (- 12 dB)					3.072	96		1.536	
#11		1	2	5	16	0x01 (+ 3.5 dB)					6.144	64	192	3.072	48
#12	7.680	1	2	5	20	0x2E (- 6.0 dB)	0	0			7.680	80	192	3.840	48

1. CICMOD = 100 for CIC order equal to 4. CICMOD = 101 for CIC order equal to 5.

27.7.2 Programming examples

Example 1

This example describes the programming of ADF for the capture of a signal coming from a digital microphone, using only the CIC4, with a decimation of 48, assuming that the kernel clock is 1.536 MHz. Typically, this configuration can be used to detect sound using the SAD.

Table 239. Programming sequence (CIC4)

Operations	Comments
Adjust the proper kernel clock frequency via the RCC	Assuming that the RCC is programmed to provide a kernel clock (adf_ker_ck) of 1.536 MHz coming from a RC oscillator.
Select the proper ADF kernel clock source via the RCC	Refer to the RCC of the product.
Enable the ADF clocks via the RCC	Refer to the RCC of the product.
Reset the ADF via the RCC	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select ADF_SD0 and ADF_CCK0 functions.
Enable ADF processing clock: ADF_CKGCR = 0x0001 0023	PROCDIV = 0 (bypass): adf_proc_ck frequency is 1.536 MHz. CCKDIV = 1 (division by 2): ADF_CCK0 clock frequency is 768 kHz. The ADF_CCK0 pin is set in output and generates a clock so that the microphone can exit from low-power mode.
Serial interfaces configuration: ADF_SITF0CR = 0x0000 1F01	SCKSRC = 0 to select ADF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER SPI mode. Clock absence feature is not working in this mode. The serial interface is enabled.
Bitstream matrix configuration: ADF_BSMX0CR = 0x0000 0000	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge
Filters configuration (CIC): ADF_DFLT0CICR = 0x0040 2F40	SCALE = 0x04 (12 dB): RSFLT is not enabled. Note that the gain is 8.5 dB, higher than recommended in order to improve signal accuracy for the SAD. Saturation is not an issue in this case, as only the detection of a signal much lower than the full scale is needed. MCICD = 0x2F (decimation by 48) CICMOD = 4 to select a $Sinc^4$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): ADF_DFLT0RSFR = 0x0000 0301	HPFC = 3: cut-off frequency of 16kHz * 0.0095 = 152 Hz HPFBYP = 0: HPF not bypassed RSFLTBYP = 1: RSFLT bypassed
Micro delay adjust: ADF_DLY0CR = 0x0000 0000	Not used in this example
Enable interrupt events: ADF_DFLT0IER = 0x0000 1000	Enable the interrupt events the application wants to handle. In this example, SDDETIE is set to 1 to have an interrupt if a sound is detected.

Table 239. Programming sequence (CIC4) (continued)

Operations	Comments
SAD setting: ADF_SADCR = 0x0000 1400	SADMOD = 1: Trigger based on sound level values FRSIZE = 4: Sound level computed on 128 samples HYSTEN = 0: No hysteresis DETCFG = 0: interrupt generated when the SAD enters in DETECT state DATCAP = 0: samples not transferred to memory SADEN = 0: SAD not yet enabled
SAD setting: ADF_SADCFGR = 0x0025 0001	ANMIN = 0x25: Sound threshold of 37 * 10^SNTHR/20 = 74 LSB(1) HGOVR = 0: four frames (4 x 128 = 512 samples) LFRNB = 0: Learning phase set to two frames. Not useful in this mode. ANSLP = 0: Not used in this mode SNTHR = 1: Threshold set to 6 dB (see ANMIN)
Clear status flags: ADF_DFLT0ISR = 0x0000 0FFF	Clear all the status flags before running the ADF
Enable the SAD: ADF_SADCR = 0x0000 1401 Wait for SADACTIVE flag = 1	Enable first the SAD, in order to be sure that data transfer to memory are blocked by the SAD.
Enable the filter: ADF_DFLT0CR = 0x0000 0001	NBDIS = 0: no samples discarded ACQMOD = 0: Asynchronous continuous acquisition mode DMAEN = 0: DMA interface not used DFLTEN = 1: Filter enabled

1. SNTHR and ANMIN values are computed using the same approach than in *Threshold programming with SADMOD = 01* (detection of a sound higher than 63 dBSPL).

Example 2

This example describes the programming of ADF for the capture of a signal coming from a digital microphone, using the CIC5, and the RSFLT, with a total decimation of 64.

Table 240. Programming sequence (CIC5)

Operations	Comments
Adjust the proper kernel clock frequency via the RCC	Assuming that the RCC is programmed to provide a kernel clock (adf_ker_ck) of 6.144 MHz
Select the proper ADF kernel clock source via the RCC	Refer to the RCC of the product.
Enable the ADF clocks via the RCC	Refer to the RCC of the product.
Reset the ADF via the RCC	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select ADF_SD0 and ADF_CCK0 functions.
Enable ADF processing clock: ADF_CKGCR = 0x0201 0023	PROCDIV = 2 (division by 3): adf_proc_ck frequency is 6.144 MHz. CCKDIV = 1 (division by 2): ADF_CCK0 clock frequency is 1.024 MHz. The ADF_CCK0 pin is set in output and generates a clock so that the microphone can exit from low-power mode.

Table 240. Programming sequence (CIC5) (continued)

Operations	Comments
Serial interfaces configuration: ADF_SITF0CR = 0x0000 1F01	SCKSRC = 0 to select ADF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER SIPI mode. Clock absence feature is not working in this mode. The serial interface is enabled.
Bitstream matrix configuration: ADF_BSMX0CR = 0x0000 0000	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge
Digital filter control: ADF_DFLT0CR = 0x0000 0006	NBDIS = 0: no samples discarded ACQMOD = 0: Asynchronous continuous acquisition mode DMAEN = 1: DMA interface not used DFLTEN = 0: Filter disabled FTH = 1: RXFIFO half-full
Filters configuration (CIC): ADF_DFLT0CICR = 0x0010 0F50	SCALE = 0x01(+3.5 dB): Output limited to 22 bits due to RSFLT. MCICD = 0xF (decimation by 16) CICMOD = 5 to select a $Sinc^5$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): ADF_DFLT0RSFR = 0x0000 0200	HPFC = 2: cut-off frequency of 16 kHz * 0.0025 = 40 Hz HPFBYP = 0: HPF not bypassed RSFLTBYP = 0: RSFLT not bypassed RSFLTD = 0: Decimation by 4
Micro delay adjust: ADF_DLY0CR = 0x0000 0000	Not used in this example
Enable interrupt events: ADF_DFLT0IER = x	Enable the interrupt events the application wants to handle.
Clear status flags: ADF_DFLT0ISR = 0x0000 0FFF	Clear all the status flags before running the ADF
Program the DMA Enable the DMA	The DMA must be programmed in order to read the data inside the ADF_DLT0DR register every time a DMA request is generated.
Start acquisition: ADF_DFLT0CR = 0x0000 0007	The ADF starts to filter data.

27.7.3 Connection examples

Figure 231 shows simple connection examples of the ADF to external sensors.

- Picture on the left: two digital microphones connected to the ADF

  In this connection, the amount of connections is optimized; DMIC1 and DMIC2 are sharing the same data line, and the same clock line. BSMX allows the application to connect the digital filter either to DMIC1 or to DMIC2. In this configuration when one of the microphone is used, the other is activated as well, as they share the same clock.
- Picture in the center: two digital microphones connected to the ADF

  In this connection, DMIC1 and DMIC2 are sharing the same data line, but have a dedicated clock line. BSMX allows the application to connect the filter either to DMIC1 or to DMIC2. When the application wants to use a microphone, it is possible to keep the other in low-power mode by forcing its clock line to 0 (CCKyEN = 0, CCKyDIR = 1).

- Picture on the right: single sensor connected to the ADF

  It is also possible to configure the CCK0 and CCK1 pins to input in order to connect sensors providing the clock.

Figure 232. Sensor connection examples

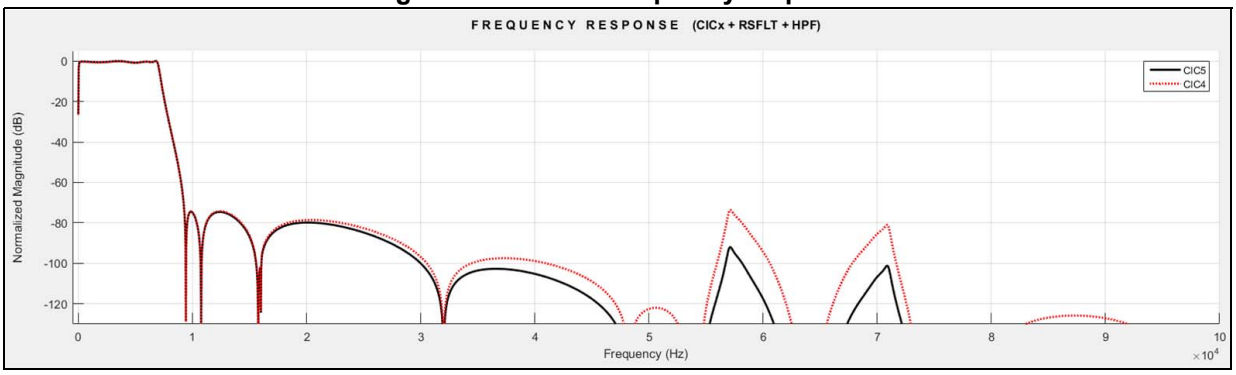
27.7.4 Global frequency response

Figure 232 shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 40 Hz

Figure 233 shows the theoretical frequency response using a CIC4 and a CIC5.

Figure 233. Global frequency response



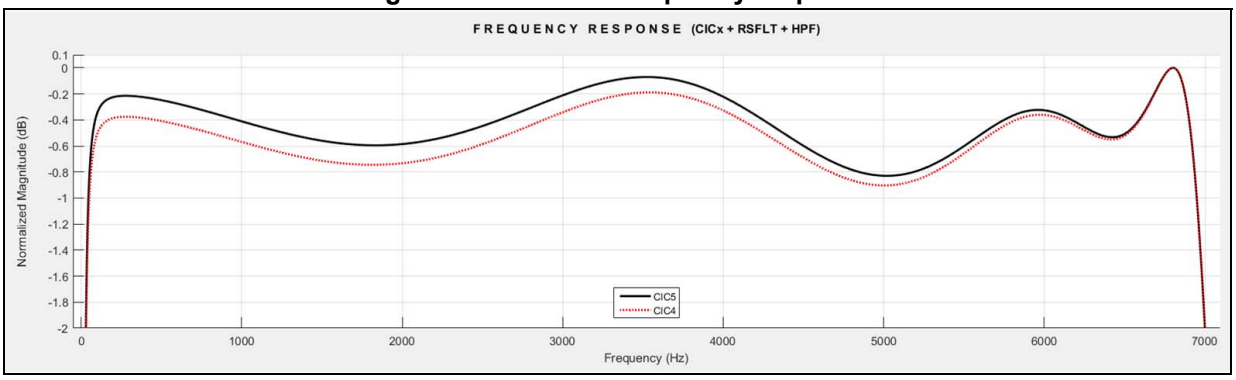


Figure 234 shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 dB for CIC4.

The - 3 dB cut-off frequency is 7061 Hz.

Figure 234. Detailed frequency response

27.7.5 Total ADF gain

This section details how to compute the signal level provided by the ADF according to the filter settings.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a − 6 dBFS level (6 dB below full scale).

For example, for the ADF offering a final data width of 24 bits, a signal having an amplitude of 2 * 10^6 LSB has a level of:

$$20 \times \log_{10}\left(\frac{2 \times 10^6}{2^{(24-1)}}\right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left(\frac{\ln(Amp)}{\ln(2)} + 1\right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of 2 * 10^6 LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain (G_{CIC} and GdB_{CIC}) can be deduced from the following formula giving data size in bits (DS_{CIC}).

$$DS_{CIC} = (N \times \log_2(D1)) + DSin$$

where N represents the CIC order (selected by CICMOD[2:0]), and D1 is the decimation ratio (given by MCICD[8:0]).

DSin represents the data size (in bits) of the signal at CIC input.

Warning: **DS_{CIC} is very important for CIC filter. In order to work fine, DS_{CIC} must not exceed 26 bits.**

The CIC gain G_{CIC} is given by:

$$G_{CIC} = (D1)^N$$

which gives in decibels:

$$GdB_{CIC} = 20 \times \log_{10}((D1)^N)$$

Data size at SCALE output

The data size at SCALE output (including the CIC gain), is a key information as the RSFLT starts to have some saturations, if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted.

The signal amplitude at SCALE output is:

$$Asout_{SCALE} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times Asin_{DFLT}$$

GdB_{SCALE} represents the gain selected by SCALE[5:0], in dB.

$Asout_{SCALE}$ is the signal amplitude at SCALE output (in LSB), and $Asin_{DFLT}$ is the signal amplitude at CIC input (LSB).

$$DS_{SCALE} = \frac{\ln(Asout_{SCALE})}{\ln(2)} + 1$$

The data size at SCALE output (DS_{SCALE}) is expressed in bits.

RSFLT gain

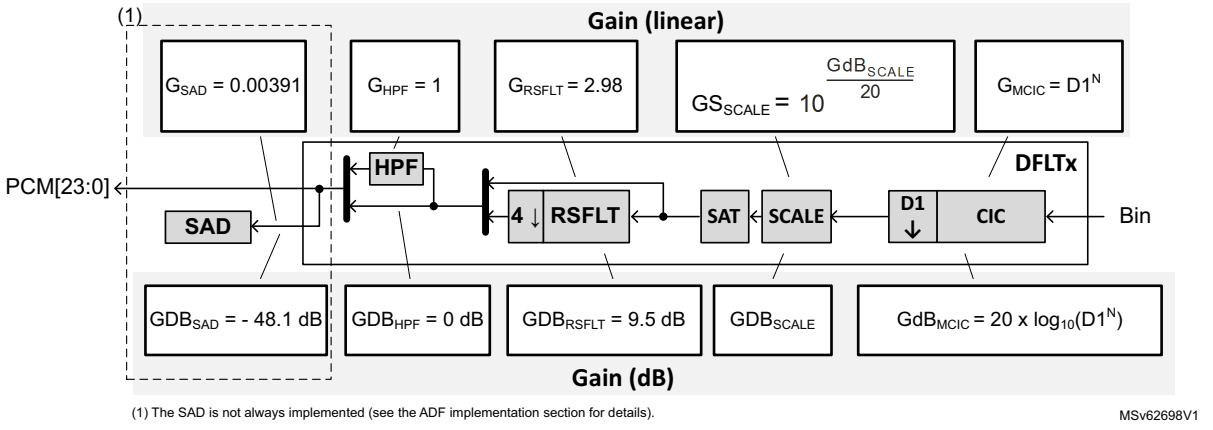
The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.41 dB must be considered.

$$G_{RSFLT} = 10^{\frac{9.5\ dB}{20}} = 2.98 \text{ typical}$$

Note: The HPF filter has a gain of 0 dB.

SAD gain

The SAD is using only the 16 MSB on the signal, as a consequence, from the SAD point of view, the truncation from 24 to 16 bits can be seen as an attenuation.



$GdB_{SAD} = -48.1dB$

and

$G_{SAD} = 0.003906$

The *Figure 235* shows a simplified view of the filter path and gives, for each significant component, the expression of the bit growth and the gain.

Figure 235. Simplified DFLT view with gain information

Note: The SAD is not always implemented (see Section 27.3 for details).

Table 241 summarizes of the final data size for different filter configurations.

Table 241. Output signal levels

Filter configurations	Final signal amplitude (LSB)
CIC + RSFLT + HPF + SAD	Samples provided to the RXFIFO: $Asout_{RXFIFO} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times Asin_{DFLT}$ Samples provided to the SAD: $Asout_{SAD} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times 0.003906 \times Asin_{DFLT}$ DS_{SCALE} must be lower than 22 bits
CIC + RSFLT (+ HPF)	$ASout_{HPF} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times Asin_{DFLT}$ DS_{SCALE} must be lower than 22 bits
CIC (+ HPF)	$ASout_{HPF} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times Asin_{DFLT}$ DS_{SCALE} must be lower than 24 bits

Example using the main filter chain

If the ADF filter is programmed as follows:

- The input signal is coming from a serial interface ($Dsin_{RSFLT}$ = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to - 12 dB.
- RSFLT enabled, and the decimation by four is enabled.
- HPF is enabled.

Check first the data size at CIC output:

$$DS_{CIC} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits}$$

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a 22-bit max signal to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$Asout_{SCALE} = 24^5 \times 10^{\frac{-12}{20}} \times 1 = 2.10^6$$

$$DS_{SCALE} = \frac{\ln(2.10^6)}{\ln(2)} + 1 = 21.93 \text{ bits}$$

If a higher gain is used, the RSFLT may saturate the output signal for strong input signals.

At the end, the final signal amplitude is:

$$Asout_{HPF} = 24^5 \times 10^{\frac{-12}{20}} \times 10^{\frac{9.5}{20}} \times 1 = 5.9711 \times 10^6$$

$$Dsout_{HPF} = \left(\frac{\ln(5.9711 \times 10^6)}{\ln(2)} + 1\right) = 23.51 \text{ bits}$$

or:

$$SDB_{OUT} = 20 \times \log_{10}\left(\frac{2^{23.51}}{2^{24}}\right) = -2.84 \text{ dBFS}$$

27.7.6 How to compute SAD thresholds

The SAD does not compute the RMS value of the converted signal, but the average of the absolute values. As a consequence, the estimated level differs from the RMS value of the signal:

- For a sine signal having an RMS value of 1, the SAD computes a level of 0.9.
- For a white or pink noise signal having an RMS value of 1, the SAD computes a level of about 0.8.

Note: FRSIZE[2:0] has a big influence on the accuracy of the level estimation: big FRSIZE[2:0] values give better results.

Threshold programming with SADMOD = 01

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 63 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02.

The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 63 dBSPL produces a digital signal of about:
- 26 dBFS - (94 - 63) = - 57 dBFS.

- SCALE value adjustment

  For this example, the filter configuration is the following:
  - CIC5 with a decimation by 16
  - RSFLT enabled with a decimation by 4
  - HPF enabled

  A SCALE value of 3.5 dB is recommended for this configuration. As DFTL0 provides samples only used for a sound detection (samples not provided to the application), a bigger gain value can be applied: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 15.6 dB).
- Input signal amplitude

  The input signal is - 57 dBFS, corresponding to an amplitude

  Asin = $10^{(-57/20)}$ = 0.00141 LSB.
- Signal level at SAD input

  The total filter gain for the SAD is:

$$G_{SAD} = 16^5 \times 10^{\frac{15.6}{20}} \times 10^{\frac{9.5}{20}} \times \frac{1}{256} = 73.68 \times 10^3 \text{ or } 97.3 \text{ dB}$$

  The signal amplitude received by the SAD is:

$$Ain_{SAD} = 0.00141 \times G_{SAD} \sim 104 \text{ LSB}$$

  The gain can be increased if the expected amplitude is too small. For the targeted application, 104 LSB is fine.

  If the input signal is expected to be a sine, the sound level for a signal amplitude of 104 LSB is:

$$SDLVL = \frac{Ain_{SAD} \times \sqrt{2}}{2} \times 0.9 \sim 66 \text{ LSB}$$

  where 0.9 is the correction factor to apply with respect to the RMS value.
- Program the trigger value

ANMIN and SNTHR must be programmed to trigger the SAD when the input signal level reaches 66 LSB.

For SADMOD[1:0] = 01, the threshold value is given by:

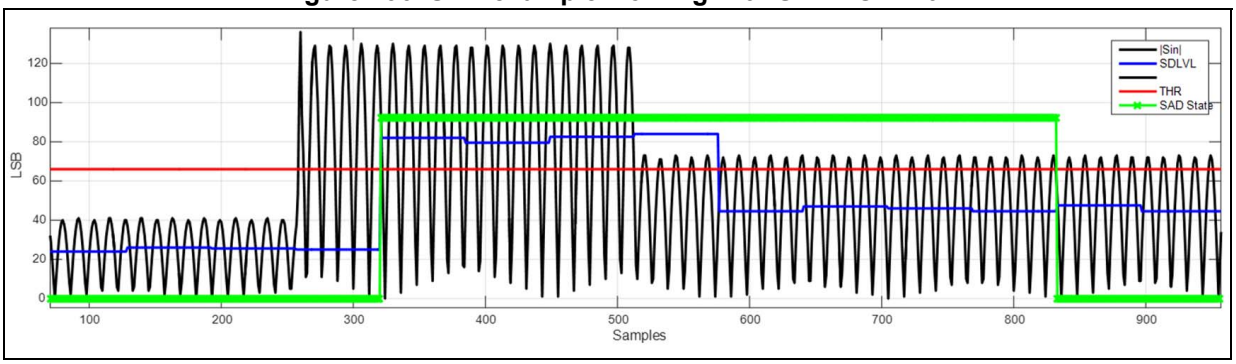
$$THRH = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}$$

where GdB_{SNTHR} represents the decibel value selected by SNTHR[3:0].

When SNTHR[3:0] = 6 dB for example, this formula becomes:

$$THRH = 2 \times ANMIN$$

So ANMIN = THRH/2 = 66 /2 = 33 LSB.



In *Figure 235*, the trigger value (THRH in red) is fixed to 66 LSB. The input signal is at - 65dBFS during 256 samples, then its value goes to - 55 dB for 256 samples, and finally it is reduced to - 60 dBFS.

The blue curve is showing the sound level estimation (SDLVL) versus time. Fluctuation on the estimated value can be observed due to windowing effect of FRSIZE samples.

The SAD DETECT state (when green signal is high) is maintained during four additional frames due to hangover function value.

In this example ANSLP = FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 33.

Figure 236. SAD example working with SADMOD = 01

Threshold programming with SADMOD = 1x

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 57 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02. The sensitivity of this microphone is typically - 26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 57 dBSPL produces a digital signal of about:
- 26 dBFS - (94-63) = - 63 dBFS.

- Adjust SCALE value

  For this example, the filter configuration is the following:

  – CIC4 with a decimation by 48

– RSFLT bypassed
– HPF enabled

A SCALE value of 3.5 dB is recommended for this configuration. The samples provided by DFTL0 are only used for a sound detection, without providing the samples to the application, a bigger gain value can be provided: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 24 dB).

- Input signal amplitude

  The input signal is - 63 dBFS, corresponding to an amplitude:

  Asin = $10^{(-63/20)}$ = 0.000708 LSB.

- Signal level at SAD input

  The total filter gain for the SAD is:

$$G_{SAD} = 48^4 \times 10^{\frac{24}{20}} \times 0.003906 = 328.6 \times 10^3 \text{ or } 110.3 \text{ dB}$$

The signal amplitude received by the SAD is:

$$Ain_{SAD} = 0.000708 \times G_{SAD} \sim 232 \text{ LSB}$$

The gain can be increased if the expected amplitude is too small.

If the input signal is expected to be a sine, the sound level for a signal amplitude of 232 LSB is:

$$SDLVL = \frac{Ain_{SAD} \times \sqrt{2}}{2} \times 0.9 \sim 148 \text{ LSB}$$

where 0.9 is the correction factor to apply with respect to the RMS value.

Note: ANLVL converges to average of SDLVL values, with a long constant time.
So SDLVL ~ ANLVL = 148 LSB for a constant input signal at 57 dBSPL.

- Programming trigger value

  For SADMOD = 1', the SAD compares the estimated ambient noise multiplied by the gain selected by SNTHR[3:0] to ANMIN[12:0] * 4.

  For simplification, SNTHR[3:0] is set to 1 (6 dB), meaning that ANLVL is multiplied by two.

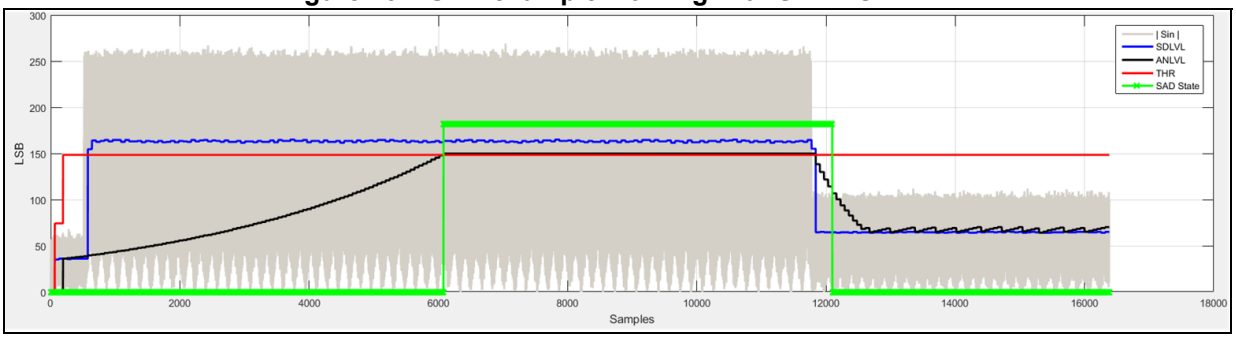
  The SAD triggers if 2 * ANLVL > THRH.

  In this mode,

$$THRH = 4 \times ANMIN$$

So the SAD triggers if:

$$ANLVL > 2 \times ANMIN$$



So ANMIN = 148 / 2 = 74 LSB

In *Figure 236*, the trigger value (THRH in red) is fixed to 148 LSB. The input signal is at - 75 dBFS during 512 samples, then its value goes to - 62 dB for 11000 samples, and finally it is reduced to - 70 dBFS.

The blue curve shows the sound level estimation (SDLVL) versus time. The black curve shows the ambient noise estimation versus time, increasing or decreasing logarithmically. During the learning phase, it reaches the SDLVL value.

In this example ANSLP = 6, FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 74.

Figure 237. SAD example working with SADMOD = 1x

27.8 ADF registers

All the ADF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

27.8.1 ADF global control register (ADF_GCR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRGO
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TRGO**: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also used to synchronize several ADF together by controlling the adf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.

1: Write 1 generates a positive pulse on the adf_trgo signal and triggers the acquisition on enabled filter having their ACQMOD[2:0] = 01x and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

27.8.2 ADF clock generator control register (ADF_CKGCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to control the clock generator. The clock adf_proc_ck must be enabled before enabling other ADF parts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CKGACTIVE	PROCDIV[6:0]							Res.	Res.	Res.	Res.	CCKDIV[3:0]			
r	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRGSRC[3:0]				Res.	Res.	Res.	TRGSENS	Res.	CCK1DIR	CCK0DIR	CKGMOD	Res.	CCK1EN	CCK0EN	CKGDEN
rw	rw	rw	rw				rw		rw	rw	rw		rw	rw	rw

Bit 31 **CKGACTIVE**: Clock generator active flag

This bit is set and cleared by hardware. Ii is used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (see *Section 27.4.13: Register protection* for details).

The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two 2 periods of adf_proc_ck.

0: The clock generator is not active and can be configured if needed.

1: The clock generator is active and protected fields cannot be configured.

Bits 30:24 **PROCDIV[6:0]**: Divider to control the serial interface clock

This bitfield is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

$$F_{adf_itf_ck} = \frac{F_{adf_ker_ck}}{(PROCDIV + 1)}$$

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

0: adf_ker_ck provided to the SITF

1: adf_ker_ck / 2 provided to the SITF

2: adf_ker_ck / 3 provided to the SITF

...

127: adf_ker_ck / 128 provided to the SITF

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the ADF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the ADF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the ADF_CCK is given by the following formula:

$$F_{ADF_CCK} = \frac{F_{adf_ker_ck}}{(PROCDIV + 1) \times (CCKDIV + 1)}$$

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

0000: The ADF_CCK clock is adf_proc_ck.

0001: The ADF_CCK clock is adf_proc_ck / 2.

0010: The ADF_CCK clock is adf_proc_ck / 3.

...

1111: The ADF_CCK clock is adf_proc_ck / 16.

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter. This bitfield is not significant if the CKGMOD = 0.

000x: TRGO selected

0010: adf_trg1 selected

Others: Reserved

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.

1: A falling edge even triggers the activation of CKGEN dividers.

Note: When the trigger source is TRGO, the sensitivity is forced to falling edge, thus TRGSENS value is not taken into account. This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: ADF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK1 pin.

0: The ADF_CCK1 pin direction is in input.

1: The ADF_CCK1 pin direction is in output.

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 5 **CCK0DIR**: ADF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK0 pin.

0: The ADF_CCK0 pin direction is in input.

1: The ADF_CCK0 pin direction is in output.

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if the filter is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.

1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: ADF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK1 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the ADF_CCK1 pin.

Bit 1 **CCK0EN**: ADF_CCK0 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK0 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the ADF_CCK0 pin

Bit 0 **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled

1: CKGEN dividers enabled

27.8.3 ADF trigger input selection register (ADF_TRGISEL)

Address offset: 0x020

Reset value: 0x0000 0000

This register is used to select the trigger signal.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **TRGISEL[2:0]**: Input selection for adf_trgi

This bitfield is used to select the signal connected to adf_trgi input. The filter(s) must be disabled (DFTEN=0) before changing this field.

000: adf_trgi0 is selected (default after reset)

001: adf_trgi1 is selected

010: adf_trgi2 is selected

011: adf_trgi3 is selected

100: adf_trgi4 is selected

Others: Reserved

Refer to *Table 224* to find signals connected to each input.

27.8.4 ADF serial interface control register 0 (ADF_SITF0CR)

Address offset: 0x080

Reset value: 0x0000 1F00

This register is used to control the serial interface SITF0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw			rw	rw		rw	rw	rw

Bit 31 **SITFACTIVE**: Serial interface active flag

This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when SITFACTIVE is set to 0 (see *Section 27.4.13: Register protection* for details).
The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of adf_proc_ck.
0: The serial interface is not active, and can be configured if needed.
1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 **STH[4:0]**: Manchester symbol threshold/SPI threshold

This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (see *Manchester mode* for details on computation).
In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SITFMOD[1:0]**: Serial interface type

This bitfield is set and cleared by software. It is used to define the serial interface type.
00: LF_MASTER SPI mode
01: Normal SPI mode
10: Manchester mode: rising edge = logic 0, falling edge = logic 1
11: Manchester mode: rising edge = logic 1, falling edge = logic 0

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source

This bitfield is set and cleared by software. It is used to select the clock source of the serial interface.
00: Serial clock source is ADF_CCK0.
01: Serial clock source is ADF_CCK1.
others: reserved

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 0 **SITFEN**: Serial interface enable

This bit is set and cleared by software. It is used to enable/disable the serial interface.

0: Serial interface disabled

1: Serial interface enabled

27.8.5 ADF bitstream matrix control register 0 (ADF_BSMX0CR)

Address offset: 0x084

Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to DFLT0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit 31 **BSMXACTIVE**: BSMX active flag

This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when BSMXACTIVE is set to 0. This BSMXACTIVE flag cannot go to 0 if DFLT0 is enabled.

0: BSMX is not active and can be configured if needed.

1: BSMX is active and protected fields cannot be configured.

Bits 30:5 Reserved, must be kept at reset value.

Bits 4:0 **BSSEL[4:0]**: Bitstream selection

This bitfield is set and cleared by software. It is used to select the bitstream to be processed for DFLT0.

00000: bs0_r provided to DFLT0

00001: bs0_f provided to DFLT0

others: reserved

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

27.8.6 ADF digital filter control register 0 (ADF_DFLT0CR)

Address offset: 0x088

Reset value: 0x0000 0000

Bit 31 **DFLTACTIVE**: DFLT0 active flag

This bit is set and cleared by hardware. It indicates if DFLT0 is active: can be running or waiting for events.

0: DFLT0 not active (can be re-enabled again, via DFLTEN bit, if needed)

1: DFLT0 active

Bit 30 **DFLTRUN**: DFLT0 run status flag

This bit is set and cleared by hardware. It indicates if DFLT0 is running or not.

0: DFLT0 not running and ready to accept a new trigger event

1: DFLT0running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **NBDIS[7:0]**: Number of samples to be discarded

This bitfield is set and cleared by software. It is used to define the number of samples to be discarded every time DFLT0 is re-started.

0: No sample discarded

1: 1 sample discarded

2: 2 samples discarded

...

255: 255 samples discarded

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:12 **TRGSRC[3:0]**: DFLT0 trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger DFLT0.

0000: TRGO selected

0010: adf_trgi selected

Others: Reserved

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: DFLT0 trigger sensitivity selection

This bitfield is set and cleared by software. It is used to select the trigger sensitivity of the external signals

0: A rising edge event triggers the acquisition.

1: A falling edge even triggers the acquisition.

Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge.
This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: DFLT0 trigger mode

This bitfield is set and cleared by software. It is used to select the filter trigger mode.

000: Asynchronous continuous acquisition mode

001: Asynchronous single-shot acquisition mode

010: Synchronous continuous acquisition mode

011: Synchronous single-shot acquisition mode

100: Window continuous acquisition mode

Others: Same as 000

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection

This bit is set and cleared by software. It is used to select the RXFIFO threshold.

0: RXFIFO threshold event generated when the RXFIFO is not empty

1: RXFIFO threshold event generated when the RXFIFO is half-full

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 1 **DMAEN**: DMA requests enable

This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.

0: DMA interface for the corresponding digital filter disabled

1: DMA interface for the corresponding digital filter enabled

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 0 **DFLTEN**: DFLT0 enable

This bit is set and cleared by software. It is used to control the start of acquisition of the DFLT0 path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped

1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x.

27.8.7 ADF digital filer configuration register 0 (ADF_DFLT0CICR)

Address offset: 0x08C

Reset value: 0x0000 0000

This register is used to control the main CIC filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SCALE[5:0]						Res.	Res.	Res.	MCICD8
						rw	rw	rw	rw	rw	rw				rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCICD[7:0]								Res.	CICMOD[2:0]			Res.	Res.	DATSRC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (see *Table 229* for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

000000: 0 dB
000001: + 3.5 dB
000010: + 6 dB or shift left by 1 bit
...
011000: + 72 dB or shift left by 12 bits
100000: - 48.2 dB or shift right by 8 bits (default value)
100001: - 44.6 dB
100010: - 42.1 dB or shift right by 7 bits
100011: - 38.6 dB
...
101110: -6 dB or shift right by 1 bit
101111: -2.5 dB
Others: Reserved

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection

This bitfield is set and cleared by software.It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).

0: Decimation ratio is 2.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4.
...
511: Decimation ratio is 512.

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC order

This bitfield is set and cleared by software. It is used to select the order of the MCIC.

100: MCIC configured in single $Sinc^4$ filter
101: MCIC configured in single $Sinc^5$ filter
Others: Reserved

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter

This bitfield is set and cleared by software.

0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

27.8.8 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)

Address offset: 0x090

Reset value: 0x0000 0000

This register is used to control the reshape and HPF filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	HPFC[1:0]		HPFBYP	Res.	Res.	RSFLTD	Res.	Res.	Res.	RSFLTBYP
						rw	rw	rw			rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **HPFC[1:0]**: High-pass filter cut-off frequency

This bitfield is set and cleared by software. it is used to select the cut-off frequency of the high-pass filter. F_{PCM} represents the sampling frequency at HPF input.

00: Cut-off frequency = 0.000625 x FPCM

01: Cut-off frequency = 0.00125 x FPCM

10: Cut-off frequency = 0.00250 x FPCM

11: Cut-off frequency = 0.00950 x FPCM

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 7 **HPFBYP**: High-pass filter bypass

This bit is set and cleared by software. It is used to bypass the high-pass filter.

0: HPF not bypassed (default value)

1: HPF bypassed

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RSFLTD**: Reshaper filter decimation ratio

This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter

0: Decimation ratio is 4 (default value).

1: Decimation ratio is 1.

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass

This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.

0: Reshape filter not bypassed (default value)

1: Reshape filter bypassed

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

27.8.9 ADF delay control register 0 (ADF_DLY0CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

This register is used for the adjustment stream delays.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SKPBF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SKPDLY[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bit 31 **SKPBF**: Skip busy flag
This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.
0: ADF ready to accept a new value into SKPDLY[6:0]
1: Last valid SKPDLY[6:0] still under precessing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 **SKPDLY[6:0]**: Delay to apply to a bitstream
This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.
0: No input sample skipped
1: 1 input sample skipped
...
127: 127 input samples skipped

27.8.10 ADF DFLT0 interrupt enable register (ADF_DFLT0IER)

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SDLVLIE	SDDETIE	RFOVRIE	CKABIE	SATIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DOVRIE	FTHIE
		rw	rw	rw	rw	rw								rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLIE**: SAD sound-level value ready enable
This bit is set and cleared by software.
0: Sound-level-ready interrupt disabled
1: Sound-level-ready interrupt enabled

Bit 12 **SDDETIE**: Sound activity detection interrupt enable
This bit is set and cleared by software.
0: Sound-trigger interrupt disabled
1: Sound-trigger interrupt enabled

Bit 11 **RFOVRIE**: Reshape filter overrun interrupt enable
This bit is set and cleared by software.
0: Reshape filter overrun interrupt disabled
1: Reshape filter overrun interrupt enabled

Bit 10 **CKABIE**: Clock absence detection interrupt enable
This bit is set and cleared by software.
0: Clock absence interrupt disabled
1: Clock absence interrupt enabled

Bit 9 **SATIE**: Saturation detection interrupt enable
This bit is set and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **DOVRIE**: Data overflow interrupt enable
This bit is set and cleared by software.
0: Data overflow interrupt disabled
1: Data overflow interrupt enabled

Bit 0 **FTHIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
0: RXFIFO threshold interrupt disabled
1: RXFIFO threshold interrupt enabled

27.8.11 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)

Address offset: 0x0B0

Reset value: 0x0000 0000

This register contains the status flags for the digital filter path.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SDLVLF	SDDETF	RFOVRF	CKABF	SATF	Res.	Res.	Res.	Res.	Res.	RXNEF	Res.	DOVRF	FTHF
		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1						r		rc_w1	r

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLF**: Sound level value ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that new sound level value is not ready. Write 0 has no effect.
1: Read 1 means that new sound level value is ready. Write 1 clears this flag.

Bit 12 **SDDETF**: Sound activity detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no sound activity is detected. Write 0 has no effect.
1: Read 1 means that sound activity is detected. Write 1 clears this flag.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **RXNEF**: RXFIFO not empty flag
This bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag
This bit is set by hardware, and cleared by the hardware when the RXFIFO level is lower than the threshold.
0: RXFIFO threshold not reached
1: RXFIFO threshold reached

27.8.12 ADF SAD control register (ADF_SADCR)

Address offset: 0x0B8

Reset value: 0x0000 0000

This register is used for the configuration and the control of the sound activity detection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SADMOD[1:0]		Res.	FRSIZE[2:0]			HYSTEN	Res.	SADST[1:0]		DETCFG	DATCAP[1:0]		SADEN
		rw	rw		rw	rw	rw	rw		r	r	rw	rw	rw	rw

Bit 31 **SADACTIVE**: SAD Active flag

This bit is set and cleared by hardware. It is used to check if the SAD is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the SADACTIVE is set to 0 (see *Section 27.4.13: Register protection* for details).

The delay between a transition on SADEN and a transition on SADACTIVE is two periods of AHB clock and two periods of adf_proc_ck.

0: SAD not active and can be configured if needed

1: SAD active and protected fields cannot be configured.

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:12 **SADMOD[1:0]**: SAD working mode

This bitfield is set and cleared by software. It is used to define the way the SAD works.

00: Threshold value computed according to the estimated ambient noise

The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a voice activity detector.

01: Threshold value equal to ANMIN[12:0], multiplied by the gain selected by SNTHR[3:0]

The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a sound detector.

1x: Threshold value given by 4 x ANMIN[12:0]

The SAD triggers when the estimated ambient noise (ANLVL), multiplied by the gain selected by SNTHR[3:0] is bigger than the defined threshold. In this mode, the SAD is working like an ambient noise estimator. Hysteresis function cannot be used in this mode.

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **FRSIZE[2:0]**: Frame size

This bitfield is set and cleared by software. it is used to define the size of one frame and also to define how many samples are taken into account to compute the short-term signal level.

000: 8 PCM samples used to compute the short-term signal level

001: 16 PCM samples used to compute the short-term signal level

010: 32 PCM samples used to compute the short-term signal level

011: 64 PCM samples used to compute the short-term signal level

100: 128 PCM samples used to compute the short-term signal level

101: 256 PCM samples used to compute the short-term signal level

11x: 512 PCM samples used to compute the short-term signal level

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 7 **HYSTEN**: Hysteresis enable

This bit is set and cleared by software. It is used to enable/disable the hysteresis function (see *Table 229* for details). This bit must be kept to 0 when SADMOD[1:0] = 1x.

0: Hysteresis function disabled. THR_H is always used.

1: Hysteresis function enabled. THR_H is used for MONITOR to DETECT transition and THR_L is used for DETECT to MONITOR transition.

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **SADST[1:0]**: SAD state

This bitfield is set and cleared by hardware. It indicates the SAD state and is meaningful only when SADEN = 1. The SAD state can be:
- LEARN when the SAD is in learning phase or in SDLVL computation mode
- MONITOR when the SAD is in monitoring phase
- DETECT when the SAD detects a sound

00: SAD in LEARN state
01: SAD in MONITOR state
11: SAD in DETECT state

Bit 3 **DETCFG**: Sound trigger event configuration

This bit is set and cleared by software. It is used to define if the sddet_evt event is generated only when the SAD enters to MONITOR state or when the SAD enters or exits the DETECT state.
0: sddet_evt generated when SAD enters the MONITOR state
1: sddet_evt generated when SAD enters or exits the DETECT state

Note: This bit can be write-protected (see Section 27.4.13: Register protection for details).

Bits 2:1 **DATCAP[1:0]**: Data capture mode

This bitfield is set and cleared by software. It is used to define in which conditions, the samples provided by DLFT0 are stored into the memory.
00: Samples from DFLT0 not transfered into the memory
01: Samples from DFLT0 transfered into the memory when SAD is in DETECT state
1x: Samples from DFLT0 transfered into memory when SAD and DFLT0 are enabled

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 0 **SADEN**: Sound activity detector enable

This bit is set and cleared by software. It is used to enable/disable the SAD.
0: SAD disabled and SAD state reset
1: SAD enabled

27.8.13 ADF SAD configuration register (ADF_SADCFGR)

Address offset: 0x0BC

Reset value: 0x0000 0000

This register is used for the configuration of the sound activity detection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	ANMIN[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HGOVR[2:0]			Res.	LFRNB[2:0]			Res.	ANSLP[2:0]			SNTHR[3:0]			
	rw	rw	rw		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **ANMIN[12:0]**: Minimum noise level

This bitfield is set and cleared by software. It is used to define the minimum noise level and then the sensitivity. It represents a positive number.

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **HGOVR[2:0]**: Hangover time window

This bitfield is set and cleared by software. Once the SAD state is DETECT, this parameter is used to define the amount of time the sound is allowed to remain below the threshold, before switching the SAD to MONITOR state (see FRSIZE bitfield for the description of a frame).

000: SAD back to MONITOR state if sound is below threshold for 4 frames
001: SAD back to MONITOR state if sound is below threshold for 8 frames
010: SAD back to MONITOR state if sound is below threshold for 16 frames
011: SAD back to MONITOR state if sound is below threshold for 32 frames
100: SAD back to MONITOR state if sound is below threshold for 64 frames
101: SAD back to MONITOR state if sound is below threshold for 128 frames
110: SAD back to MONITOR state if sound is below threshold for 256 frames
111: SAD back to MONITOR state if sound is below threshold for 512 frames

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LFRNB[2:0]**: Number of learning frames

This bitfield is set and cleared by software. It is used to define the number of learning frames to perform the first estimate of the noise level.

000: 2 frames used to compute the initial noise level
001: 4 frames used to compute the initial noise level
010: 8 frames used to compute the initial noise level
011: 16 frames used to compute the initial noise level
1xx: 32 frames used to compute the initial noise level

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ANSLP[2:0]**: Ambient noise slope control

This bitfield is set and cleared by software. It is used to define the positive and negative slope of the noise estimator, in charge of updating the ANLVL (see *Ambient noise estimation (ANLVL)* for information about programming this bitfield).

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

Bits 3:0 **SNTHR[3:0]**: Signal to noise threshold

This bitfield is set and cleared by software. It is used to define THR_H (and THR_L if hysteresis is enabled). See *Table 229* for details.

0000: THR_H is 3.5 dB higher than ANLVL
0001: THR_H is 6.0 dB higher than ANLVL
0010: THR_H is 9.5 dB higher than ANLVL
0011: THR_H is 12 dB higher than ANLVL
0100: THR_H is 15.6 dB higher than ANLVL
0101: THR_H is 18 dB higher than ANLVL
0110: THR_H is 21.6 dB higher than ANLVL
0111: THR_H is 24.1 dB higher than ANLVL
1000: THR_H is 27.6 dB higher than ANLVL
1001: THR_H is 30.1dB higher than ANLVL
others: Reserved

Note: This bitfield can be write-protected (see Section 27.4.13: Register protection for details).

27.8.14 ADF SAD sound level register (ADF_SADSDLVR)

Address offset: 0x0C0

Reset value: 0x0000 0000

This register contains the short-term sound-level computed by the SAD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	SDLVL[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **SDLVL[14:0]**: Short term sound level

This bitfield is set by hardware. It contains the latest sound level computed by the SAD. To refresh this value, SDLVLF must be cleared.

27.8.15 ADF SAD ambient noise level register (ADF_SADANLVR)

Address offset: 0x0C4

Reset value: 0x0000 0000

This register contains the ambient noise level computed by the SAD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ANLVL[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **ANLVL[14:0]**: Ambient noise level estimation

This bitfield is set by hardware. It contains the latest ambient noise level computed by the SAD. To refresh this bitfield, the SDLVLF flag must be cleared.

27.8.16 ADF digital filter data register 0 (ADF_DFLT0DR)

Address offset: 0x0F0

Reset value: 0x0000 0000

This register is used to read the data processed by the digital filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28 Touch sensing controller (TSC)

28.1 Introduction

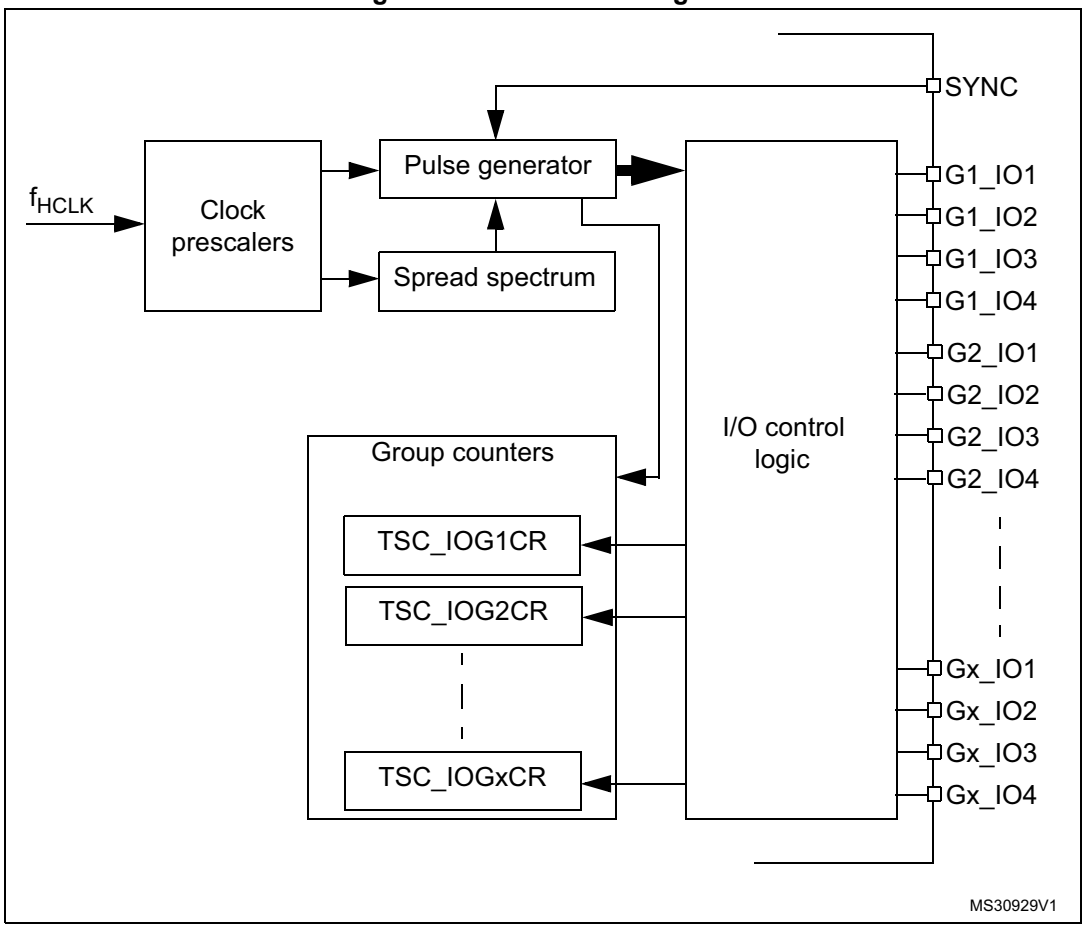
The touch sensing controller provides a simple solution for adding capacitive sensing functionality to any application. Capacitive sensing technology is able to detect finger presence near an electrode that is protected from direct touch by a dielectric (for example glass, plastic). The capacitive variation introduced by the finger (or any conductive object) is measured using a proven implementation based on a surface charge transfer acquisition principle.

The touch sensing controller is fully supported by the STMTouch touch sensing firmware library, which is free to use and allows touch sensing functionality to be implemented reliably in the end application.

28.2 TSC main features

The touch sensing controller has the following main features:

- Proven and robust surface charge transfer acquisition principle
- Supports up to 21 capacitive sensing channels without active shield
- Up to 7 capacitive sensing channels can be acquired in parallel offering a very good response time
- Spread spectrum feature to improve system robustness in noisy environments
- Full hardware management of the charge transfer acquisition sequence
- Programmable charge transfer frequency
- Programmable sampling capacitor I/O pin
- Programmable channel I/O pin
- Programmable max count value to avoid long acquisition when a channel is faulty
- Dedicated end of acquisition and max count error flags with interrupt capability
- One sampling capacitor for up to 3 capacitive sensing channels to reduce the system components
- Compatible with proximity, touchkey, linear and rotary touch sensor implementation
- Designed to operate with STMTouch touch sensing firmware library



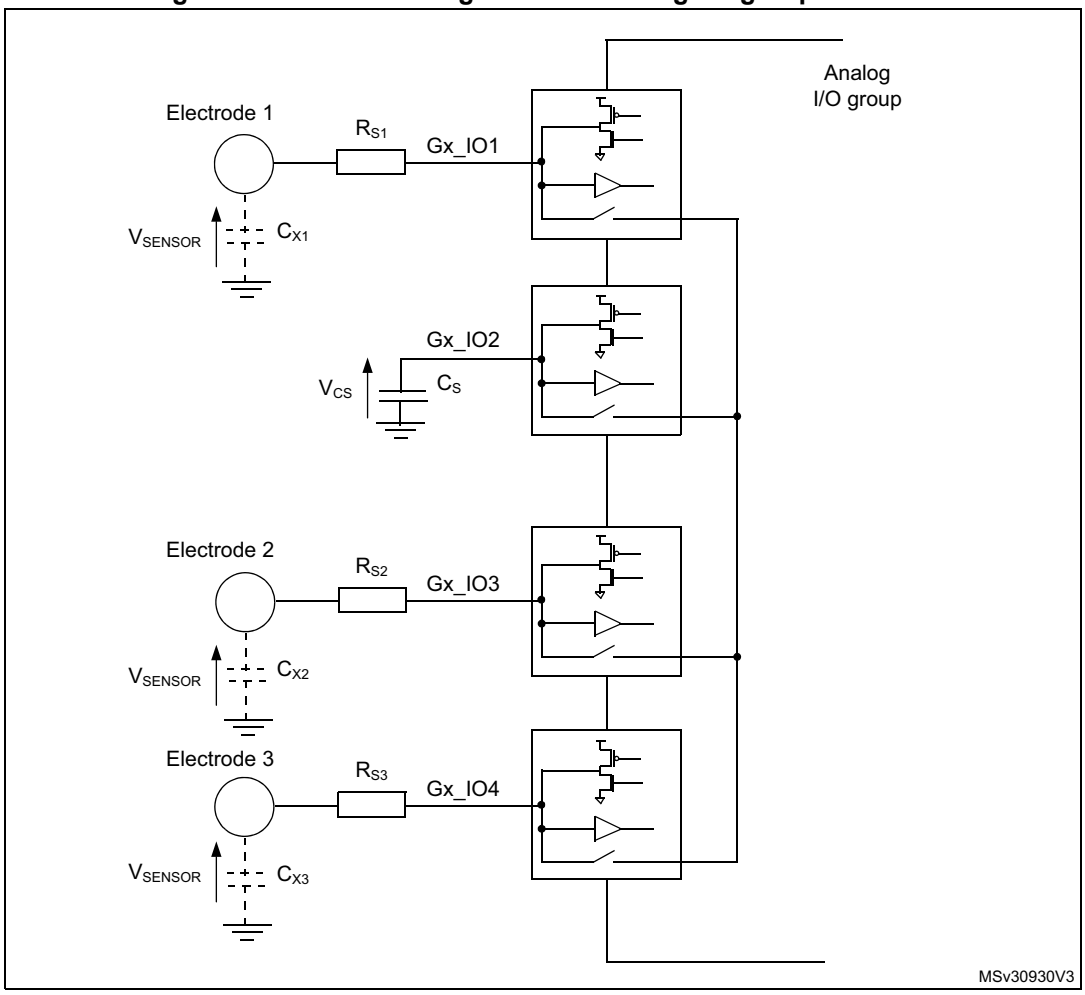
Note: The number of capacitive sensing channels is dependent on the size of the packages and subject to I/O availability.

28.3 TSC functional description

28.3.1 TSC block diagram

The block diagram of the touch sensing controller is shown in *Figure 238*.

Figure 238. TSC block diagram



28.3.2 Surface charge transfer acquisition overview

The surface charge transfer acquisition is a proven, robust and efficient way to measure a capacitance. It uses a minimum number of external components to operate with a single ended electrode type. This acquisition is designed around an analog I/O group composed of up to four GPIOs (see *Figure 239*). Several analog I/O groups are available to allow the acquisition of several capacitive sensing channels simultaneously and to support a larger number of capacitive sensing channels. Within a same analog I/O group, the acquisition of the capacitive sensing channels is sequential.

One of the GPIOs is dedicated to the sampling capacitor C_S. Only one sampling capacitor I/O per analog I/O group must be enabled at a time.

The remaining GPIOs are dedicated to the electrodes and are commonly called channels. For some specific needs (such as proximity detection), it is possible to simultaneously enable more than one channel per analog I/O group.

Figure 239. Surface charge transfer analog I/O group structure

Note: Gx_IOy where x is the analog I/O group number and y the GPIO number within the selected group.

The surface charge transfer acquisition principle consists of charging an electrode capacitance (C_X) and transferring a part of the accumulated charge into a sampling capacitor (C_S). This sequence is repeated until the voltage across C_S reaches a given threshold (V_{IH} in our case). The number of charge transfers required to reach the threshold is a direct representation of the size of the electrode capacitance.

Table 243 details the charge transfer acquisition sequence of the capacitive sensing channel 1. States 3 to 7 are repeated until the voltage across C_S reaches the given threshold. The same sequence applies to the acquisition of the other channels. The electrode serial resistor R_S improves the ESD immunity of the solution.

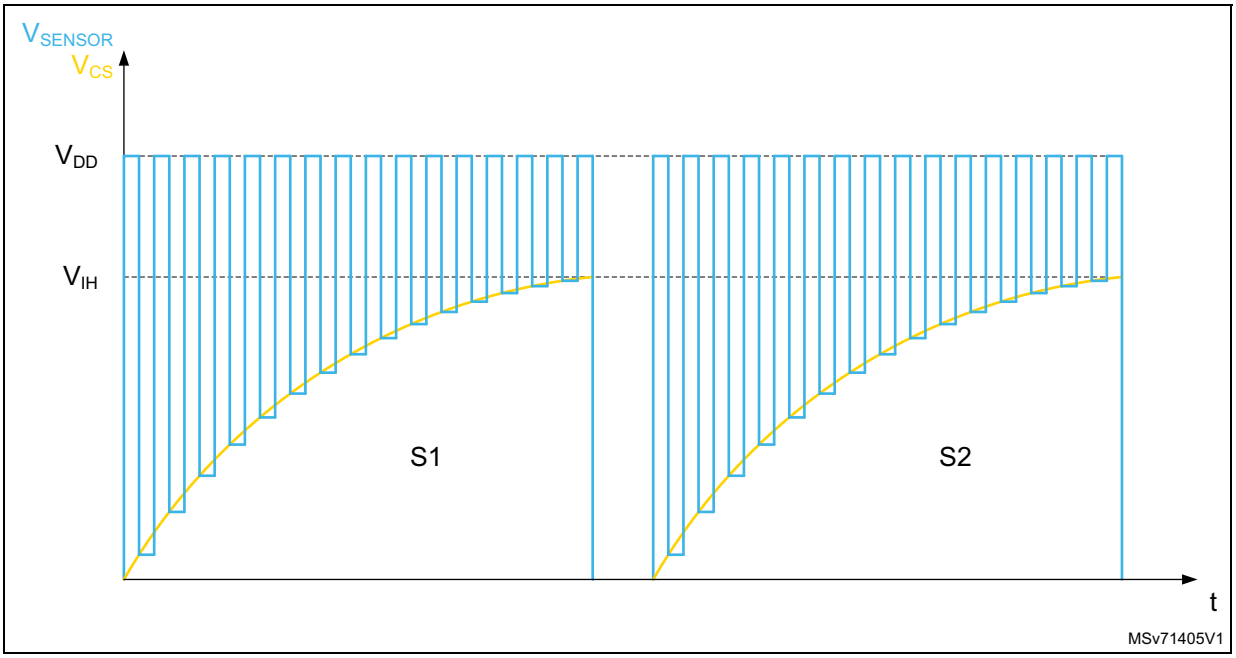


Table 243. Acquisition sequence summary

State	Gx_IO1 (channel)	Gx_IO2 (sampling)	Gx_IO3 (channel)	Gx_IO4 (channel)	State description
#1	Input floating with analog switch closed	Output open-drain low with analog switch closed	Input floating with analog switch closed		Discharge all C_X and C_S
#2	Input floating				Dead time
#3	Output push-pull high	Input floating			Charge C_{X1}
#4	Input floating				Dead time
#5	Input floating with analog switch closed		Input floating		Charge transfer from C_{X1} to C_S
#6	Input floating				Dead time
#7	Input floating				Measure C_S voltage

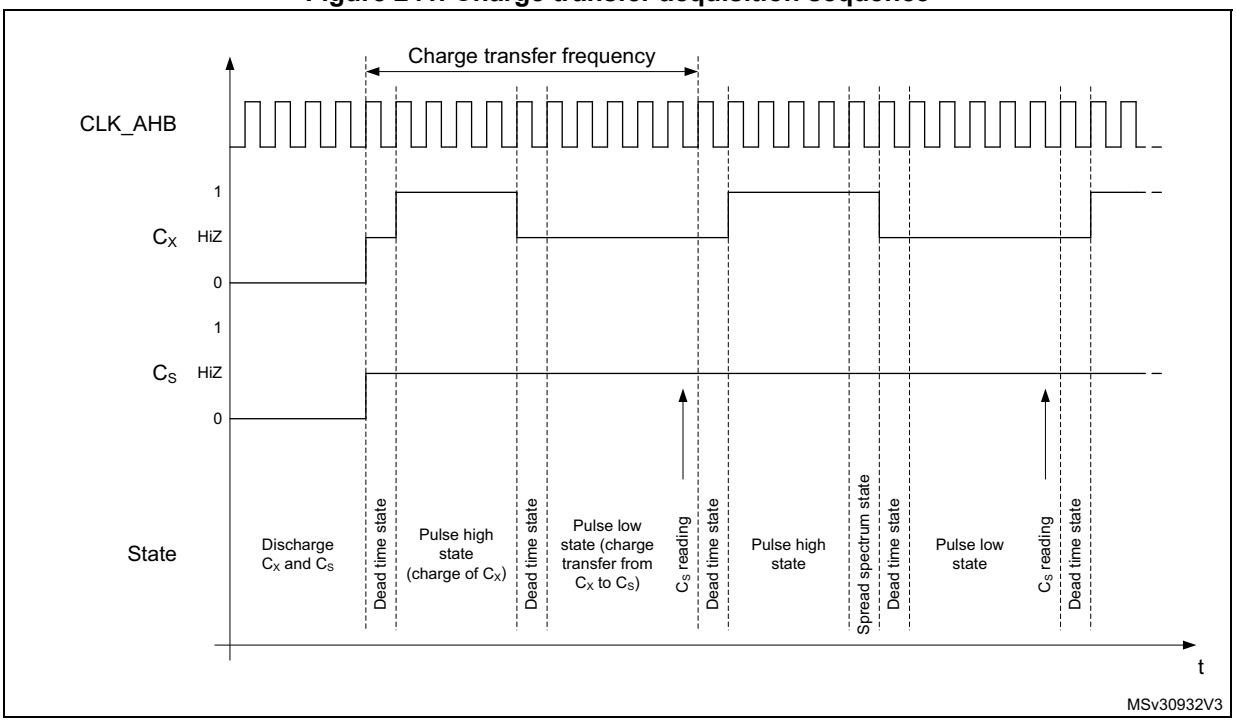
Note: Gx_IOy where x is the analog I/O group number and y the GPIO number within the selected group.

The voltage variation over the time on the sampling capacitor C_S is detailed below (refer to *Figure 239* for V_{SENSOR} and V_{CS} definition):

Figure 240. Sampling capacitor voltage variation

28.3.3 Reset and clocks

The TSC clock source is the AHB clock (HCLK). Two programmable prescalers are used to generate the pulse generator and the spread spectrum internal clocks:



- The pulse generator clock (PGCLK) is defined using the PGPSC[2:0] bits of the TSC_CR register
- The spread spectrum clock (SSCLK) is defined using the SSPSC bit of the TSC_CR register

The reset and clock controller (RCC) provides dedicated bits to enable the touch sensing controller clock and to reset this peripheral. For more information, refer to *Section 10: Reset and clock control (RCC)*.

28.3.4 Charge transfer acquisition sequence

An example of a charge transfer acquisition sequence is detailed in *Figure 241*.

Figure 241. Charge transfer acquisition sequence

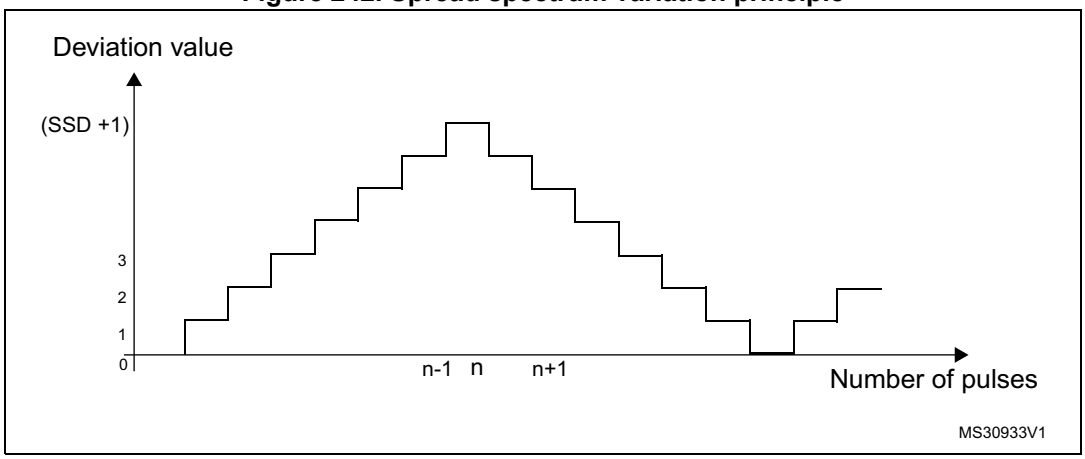
For higher flexibility, the charge transfer frequency is fully configurable. Both the pulse high state (charge of C_X) and the pulse low state (transfer of charge from C_X to C_S) duration can be defined using the CTPH[3:0] and CTPL[3:0] bits in the TSC_CR register. The standard range for the pulse high and low states duration is 500 ns to 2 µs. To ensure a correct measurement of the electrode capacitance, the pulse high state duration must be set to ensure that C_X is always fully charged.

A dead time where both the sampling capacitor I/O and the channel I/O are in input floating state is inserted between the pulse high and low states to ensure an optimum charge transfer acquisition sequence. This state duration is 1 period of HCLK.

At the end of the pulse high state and if the spread spectrum feature is enabled, a variable number of periods of the SSCLK clock are added.

The reading of the sampling capacitor I/O, to determine if the voltage across C_S has reached the given threshold, is performed at the end of the pulse low state.

Note: The following TSC control register configurations are forbidden:



- *bits PGPSC are set to 000 and bits CTPL are set to 0001*
- *bits PGPSC are set to 001 and bits CTPL are set to 0000*

28.3.5 Spread spectrum feature

The spread spectrum feature generates a variation of the charge transfer frequency. This is done to improve the robustness of the charge transfer acquisition in noisy environments and also to reduce the induced emission. The maximum frequency variation is in the range of 10% to 50% of the nominal charge transfer period. For instance, for a nominal charge transfer frequency of 250 kHz (4 µs), the typical spread spectrum deviation is 10% (400 ns) which leads to a minimum charge transfer frequency of ~227 kHz.

In practice, the spread spectrum consists of adding a variable number of SSCLK periods to the pulse high state using the principle shown below:

Figure 242. Spread spectrum variation principle

The table below details the maximum frequency deviation with different HCLK settings:

Table 244. Spread spectrum deviation versus AHB clock frequency

f_{HCLK}	Spread spectrum step	Maximum spread spectrum deviation
24 MHz	41.6 ns	10666.6 ns
48 MHz	20.8 ns	5333.3 ns

The spread spectrum feature can be disabled/enabled using the SSE bit in the TSC_CR register. The frequency deviation is also configurable to accommodate the device HCLK clock frequency and the selected charge transfer frequency through the SSPSC and SSD[6:0] bits in the TSC_CR register.

28.3.6 Max count error

The max count error prevents long acquisition times resulting from a faulty capacitive sensing channel. It consists of specifying a maximum count value for the analog I/O group counters. This maximum count value is specified using the MCV[2:0] bits in the TSC_CR register. As soon as an acquisition group counter reaches this maximum value, the ongoing acquisition is stopped and the end of acquisition (EOAF bit) and max count error (MCEF bit) flags are both set. An interrupt can also be generated if the corresponding end of acquisition (EOAIE bit) or/and max count error (MCEIE bit) interrupt enable bits are set.

28.3.7 Sampling capacitor I/O and channel I/O mode selection

To allow the GPIOs to be controlled by the touch sensing controller, the corresponding alternate function must be enabled through the standard GPIO registers and the GPIOxAFR registers.

The GPIOs modes controlled by the TSC are defined using the TSC_IOSCR and TSC_IOCCR register.

When there is no ongoing acquisition, all the I/Os controlled by the touch sensing controller are in default state. While an acquisition is ongoing, only unused I/Os (neither defined as sampling capacitor I/O nor as channel I/O) are in default state. The IODEF bit in the TSC_CR register defines the configuration of the I/Os which are in default state. The table below summarizes the configuration of the I/O depending on its mode.

Table 245. I/O state depending on its mode and IODEF bit value

IODEF bit	Acquisition status	Unused I/O mode	Channel I/O mode	Sampling capacitor I/O mode
0 (output push-pull low)	No	Output push-pull low	Output push-pull low	Output push-pull low
0 (output push-pull low)	Ongoing	Output push-pull low	-	-
1 (input floating)	No	Input floating	Input floating	Input floating
1 (input floating)	Ongoing	Input floating	-	-

Unused I/O mode

An unused I/O corresponds to a GPIO controlled by the TSC peripheral but not defined as an electrode I/O nor as a sampling capacitor I/O.

Sampling capacitor I/O mode

To allow the control of the sampling capacitor I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output open drain mode and then the corresponding Gx_IOy bit in the TSC_IOSCR register must be set.

Only one sampling capacitor per analog I/O group must be enabled at a time.

Channel I/O mode

To allow the control of the channel I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output push-pull mode and the corresponding Gx_IOy bit in the TSC_IOCCR register must be set.

For proximity detection where a higher equivalent electrode surface is required or to speed-up the acquisition process, it is possible to enable and simultaneously acquire several channels belonging to the same analog I/O group.

Note: During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR or TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.

28.3.8 Acquisition mode

The touch sensing controller offers two acquisition modes:

- Normal acquisition mode: the acquisition starts as soon as the START bit in the TSC_CR register is set.
- Synchronized acquisition mode: the acquisition is enabled by setting the START bit in the TSC_CR register but only starts upon the detection of a falling edge or a rising edge and high level on the SYNC input pin. This mode is useful for synchronizing the capacitive sensing channels acquisition with an external signal without additional CPU load.

The GxE bits in the TSC_IOGCSR registers specify which analog I/O groups are enabled (corresponding counter is counting). The C_S voltage of a disabled analog I/O group is not monitored and this group does not participate in the triggering of the end of acquisition flag. However, if the disabled analog I/O group contains some channels, they are pulsed.

When the C_S voltage of an enabled analog I/O group reaches the given threshold, the corresponding GxS bit of the TSC_IOGCSR register is set. When the acquisition of all enabled analog I/O groups is complete (all GxS bits of all enabled analog I/O groups are set), the EOAF flag in the TSC_ISR register is set. An interrupt request is generated if the EOAIE bit in the TSC_IER register is set.

In the case that a max count error is detected, the ongoing acquisition is stopped and both the EOAF and MCEF flags in the TSC_ISR register are set. Interrupt requests can be generated for both events if the corresponding bits (EOAIE and MCEIE bits of the TSCIER register) are set. Note that when the max count error is detected the remaining GxS bits in the enabled analog I/O groups are not set.

To clear the interrupt flags, the corresponding EOAIC and MCEIC bits in the TSC_ICR register must be set.

The analog I/O group counters are cleared when a new acquisition is started. They are updated with the number of charge transfer cycles generated on the corresponding channel(s) upon the completion of the acquisition.

28.3.9 I/O hysteresis and analog switch control

In order to offer a higher flexibility, the touch sensing controller is able to take the control of the Schmitt trigger hysteresis and analog switch of each Gx_IOy. This control is available whatever the I/O control mode is (controlled by standard GPIO registers or other peripherals) assuming that the touch sensing controller is enabled. This may be useful to perform a different acquisition sequence or for other purposes.

In order to improve the system immunity, the Schmitt trigger hysteresis of the GPIOs controlled by the TSC must be disabled by resetting the corresponding Gx_IOy bit in the TSC_IOHCR register.

28.4 TSC low-power modes

Table 246. Effect of low-power modes on TSC

Mode	Description
Sleep	No effect. Peripheral interrupts cause the device to exit Sleep mode.
Stop	Peripheral registers content is kept.
Standby	Powered-down. The peripheral must be reinitialized after exiting Standby mode.

28.5 TSC interrupts

Table 247. Interrupt control bits

Interrupt event	Enable control bit	Event flag	Clear flag bit	Exit the Sleep mode	Exit the Stop mode	Exit the Standby mode
End of acquisition	EOAIE	EOAIF	EOAIC	Yes	No	No
Max count error	MCEIE	MCEIF	MCEIC	Yes	No	No

28.6 TSC registers

Refer to *Section 1.2* of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

28.6.1 TSC control register (TSC_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CTPH[3:0]				CTPL[3:0]				SSD[6:0]							SSE
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSPSC	PGPSC[2:0]			Res.	Res.	Res.	Res.	MCV[2:0]			IODEF	SYNC POL	AM	START	TSCE
rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **CTPH[3:0]**: Charge transfer pulse high

These bits are set and cleared by software. They define the duration of the high state of the charge transfer pulse (charge of C_X).

0000: 1x t_{PGCLK}
0001: 2x t_{PGCLK}
...
1111: 16x t_{PGCLK}

Note: These bits must not be modified when an acquisition is ongoing.

Bits 27:24 **CTPL[3:0]**: Charge transfer pulse low

These bits are set and cleared by software. They define the duration of the low state of the charge transfer pulse (transfer of charge from C_X to C_S).

0000: 1x t_{PGCLK}
0001: 2x t_{PGCLK}
...
1111: 16x t_{PGCLK}

Note: These bits must not be modified when an acquisition is ongoing.

Note: Some configurations are forbidden. Refer to the Section 28.3.4: Charge transfer acquisition sequence for details.

Bits 23:17 **SSD[6:0]**: Spread spectrum deviation

These bits are set and cleared by software. They define the spread spectrum deviation which consists in adding a variable number of periods of the SSCLK clock to the charge transfer pulse high state.

0000000: 1x t_{SSCLK}
0000001: 2x t_{SSCLK}
...
1111111: 128x t_{SSCLK}

Note: These bits must not be modified when an acquisition is ongoing.

Bit 16 **SSE**: Spread spectrum enable

This bit is set and cleared by software to enable/disable the spread spectrum feature.

0: Spread spectrum disabled
1: Spread spectrum enabled

Note: This bit must not be modified when an acquisition is ongoing.

Bit 15 **SSPSC**: Spread spectrum prescaler

This bit is set and cleared by software. It selects the AHB clock divider used to generate the spread spectrum clock (SSCLK).

0: f_{HCLK}
1: f_{HCLK} /2

Note: This bit must not be modified when an acquisition is ongoing.

Bits 14:12 **PGPSC[2:0]**: Pulse generator prescaler

These bits are set and cleared by software.They select the AHB clock divider used to generate the pulse generator clock (PGCLK).

000: f_{HCLK}
001: f_{HCLK} /2
010: f_{HCLK} /4
011: f_{HCLK} /8
100: f_{HCLK} /16
101: f_{HCLK} /32
110: f_{HCLK} /64
111: f_{HCLK} /128

Note: These bits must not be modified when an acquisition is ongoing.

Note: Some configurations are forbidden. Refer to the Section 28.3.4: Charge transfer acquisition sequence for details.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:5 **MCV[2:0]**: Max count value

These bits are set and cleared by software. They define the maximum number of charge transfer pulses that can be generated before a max count error is generated.

000: 255
001: 511
010: 1023
011: 2047
100: 4095
101: 8191
110: 16383
111: reserved

Note: These bits must not be modified when an acquisition is ongoing.

Bit 4 **IODEF**: I/O Default mode

This bit is set and cleared by software. It defines the configuration of all the TSC I/Os when there is no ongoing acquisition. When there is an ongoing acquisition, it defines the configuration of all unused I/Os (not defined as sampling capacitor I/O or as channel I/O).

0: I/Os are forced to output push-pull low
1: I/Os are in input floating

Note: This bit must not be modified when an acquisition is ongoing.

Bit 3 **SYNCPOL**: Synchronization pin polarity

This bit is set and cleared by software to select the polarity of the synchronization input pin.

0: Falling edge only
1: Rising edge and high level

Bit 2 **AM**: Acquisition mode

This bit is set and cleared by software to select the acquisition mode.

0: Normal acquisition mode (acquisition starts as soon as START bit is set)

1: Synchronized acquisition mode (acquisition starts if START bit is set and when the selected signal is detected on the SYNC input pin)

Note: This bit must not be modified when an acquisition is ongoing.

Bit 1 **START**: Start a new acquisition

This bit is set by software to start a new acquisition. It is cleared by hardware as soon as the acquisition is complete or by software to cancel the ongoing acquisition.

0: Acquisition not started

1: Start a new acquisition

Bit 0 **TSCE**: Touch sensing controller enable

This bit is set and cleared by software to enable/disable the touch sensing controller.

0: Touch sensing controller disabled

1: Touch sensing controller enabled

Note: When the touch sensing controller is disabled, TSC registers settings have no effect.

28.6.2 TSC interrupt enable register (TSC_IER)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEIE**: Max count error interrupt enable

This bit is set and cleared by software to enable/disable the max count error interrupt.

0: Max count error interrupt disabled

1: Max count error interrupt enabled

Bit 0 **EOAIE**: End of acquisition interrupt enable

This bit is set and cleared by software to enable/disable the end of acquisition interrupt.

0: End of acquisition interrupt disabled

1: End of acquisition interrupt enabled

28.6.3 TSC interrupt clear register (TSC_ICR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCEIC	EOAIC
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEIC**: Max count error interrupt clear

This bit is set by software to clear the max count error flag and it is cleared by hardware when the flag is reset. Writing a 0 has no effect.

0: No effect

1: Clears the corresponding MCEF of the TSC_ISR register

Bit 0 **EOAIC**: End of acquisition interrupt clear

This bit is set by software to clear the end of acquisition flag and it is cleared by hardware when the flag is reset. Writing a 0 has no effect.

0: No effect

1: Clears the corresponding EOAF of the TSC_ISR register

28.6.4 TSC interrupt status register (TSC_ISR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCEF	EOAF
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEF**: Max count error flag

This bit is set by hardware as soon as an analog I/O group counter reaches the max count value specified. It is cleared by software writing 1 to the bit MCEIC of the TSC_ICR register.

0: No max count error (MCE) detected

1: Max count error (MCE) detected

Bit 0 **EOAF**: End of acquisition flag

This bit is set by hardware when the acquisition of all enabled group is complete (all GxS bits of all enabled analog I/O groups are set or when a max count error is detected). It is cleared by software writing 1 to the bit EOAIC of the TSC_ICR register.

0: Acquisition is ongoing or not started

1: Acquisition is complete

28.6.5 TSC I/O hysteresis control register (TSC_IOHCR)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	G7_IO4	G7_IO3	G7_IO2	G7_IO1	G6_IO4	G6_IO3	G6_IO2	G6_IO1	G5_IO4	G5_IO3	G5_IO2	G5_IO1
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
G4_IO4	G4_IO3	G4_IO2	G4_IO1	G3_IO4	G3_IO3	G3_IO2	G3_IO1	G2_IO4	G2_IO3	G2_IO2	G2_IO1	G1_IO4	G1_IO3	G1_IO2	G1_IO1
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **Gx_IOy**: Gx_IOy Schmitt trigger hysteresis mode

These bits are set and cleared by software to enable/disable the Gx_IOy Schmitt trigger hysteresis.

0: Gx_IOy Schmitt trigger hysteresis disabled

1: Gx_IOy Schmitt trigger hysteresis enabled

Note: These bits control the I/O Schmitt trigger hysteresis whatever the I/O control mode is (even if controlled by standard GPIO registers).

28.6.6 TSC I/O analog switch control register (TSC_IOASCR)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	G7_IO4	G7_IO3	G7_IO2	G7_IO1	G6_IO4	G6_IO3	G6_IO2	G6_IO1	G5_IO4	G5_IO3	G5_IO2	G5_IO1
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
G4_IO4	G4_IO3	G4_IO2	G4_IO1	G3_IO4	G3_IO3	G3_IO2	G3_IO1	G2_IO4	G2_IO3	G2_IO2	G2_IO1	G1_IO4	G1_IO3	G1_IO2	G1_IO1
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **Gx_IOy**: Gx_IOy analog switch enable

These bits are set and cleared by software to enable/disable the Gx_IOy analog switch.

0: Gx_IOy analog switch disabled (opened)

1: Gx_IOy analog switch enabled (closed)

Note: These bits control the I/O analog switch whatever the I/O control mode is (even if controlled by standard GPIO registers).

28.6.7 TSC I/O sampling control register (TSC_IOSCR)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	G7_IO4	G7_IO3	G7_IO2	G7_IO1	G6_IO4	G6_IO3	G6_IO2	G6_IO1	G5_IO4	G5_IO3	G5_IO2	G5_IO1
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
G4_IO4	G4_IO3	G4_IO2	G4_IO1	G3_IO4	G3_IO3	G3_IO2	G3_IO1	G2_IO4	G2_IO3	G2_IO2	G2_IO1	G1_IO4	G1_IO3	G1_IO2	G1_IO1
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **Gx_IOy**: Gx_IOy sampling mode

These bits are set and cleared by software to configure the Gx_IOy as a sampling capacitor I/O. Only one I/O per analog I/O group must be defined as sampling capacitor.

0: Gx_IOy unused

1: Gx_IOy used as sampling capacitor

Note: These bits must not be modified when an acquisition is ongoing.

During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.

28.6.8 TSC I/O channel control register (TSC_IOCCR)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	G7_IO4	G7_IO3	G7_IO2	G7_IO1	G6_IO4	G6_IO3	G6_IO2	G6_IO1	G5_IO4	G5_IO3	G5_IO2	G5_IO1
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
G4_IO4	G4_IO3	G4_IO2	G4_IO1	G3_IO4	G3_IO3	G3_IO2	G3_IO1	G2_IO4	G2_IO3	G2_IO2	G2_IO1	G1_IO4	G1_IO3	G1_IO2	G1_IO1
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **Gx_IOy**: Gx_IOy channel mode

These bits are set and cleared by software to configure the Gx_IOy as a channel I/O.

0: Gx_IOy unused

1: Gx_IOy used as channel

Note: These bits must not be modified when an acquisition is ongoing.

During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.

28.6.9 TSC I/O group control status register (TSC_IOGCSR)

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	G7S	G6S	G5S	G4S	G3S	G2S	G1S
									r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	G7E	G6E	G5E	G4E	G3E	G2E	G1E
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **GxS**: Analog I/O group x status

These bits are set by hardware when the acquisition on the corresponding enabled analog I/O group x is complete. They are cleared by hardware when a new acquisition is started.

0: Acquisition on analog I/O group x is ongoing or not started

1: Acquisition on analog I/O group x is complete

Note: When a max count error is detected the remaining GxS bits of the enabled analog I/O groups are not set.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **GxE**: Analog I/O group x enable

These bits are set and cleared by software to enable/disable the acquisition (counter is counting) on the corresponding analog I/O group x.

0: Acquisition on analog I/O group x disabled

1: Acquisition on analog I/O group x enabled

28.6.10 TSC I/O group x counter register (TSC_IOGxCR)

x represents the analog I/O group number.

Address offset: 0x30 + 0x04 * x, (x = 1 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

29 Coupling and chaining bridge (CCB)

29.1 CCB introduction

The coupling and chaining bridge (CCB) is a sophisticated security mechanism designed to ensure that private keys are protected, even against CPU access, and are wrapped with unique device keys, and stored securely in a secure storage.

The CCB can be programmed to implement special coupling and chaining operations required to protect private keys used in PKA protected operations.

These coupling and chaining operations involve the PKA, the SAES, and sometimes the RNG peripherals.

29.2 CCB main features

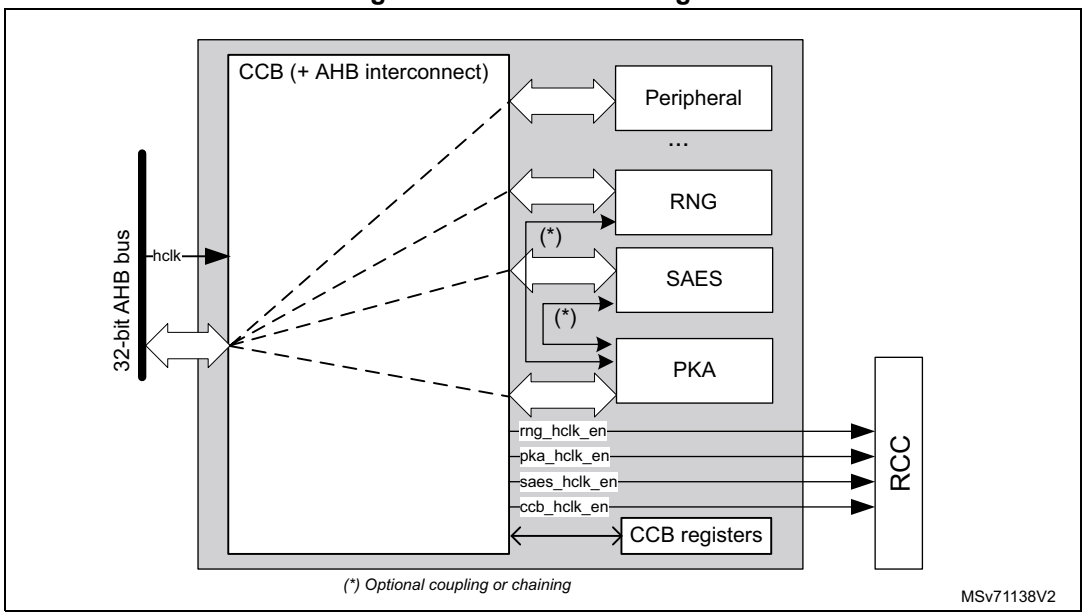
- AHB system slave port, mapping multiple peripherals (see *Section 29.3*)
- AHB configuration slave port (CCB peripheral)
  - All read accesses supported
  - 32-bit word write accesses only (otherwise an AHB error occurs)
- Optional coupling of PKA RAM writes to SAES input data register
- Support for multiple optional chaining options:
  - Read and write chaining between PKA RAM and SAES
  - SAES to CCB read chaining, with comparison to a 128-bit reference tag
  - RNG output chaining with either PKA RAM or SAES_IVR registers
- Dedicated sequences to support three PKA protected operations (modular exponentiation, scalar multiplication, ECDSA signature)
  - One-time sequence to prepare a PKA protected operation (blob creation)
  - Many-time sequence to execute PKA protected operation (blob usage)
- Optional private key generation for ECDSA signature, and for ECC private key cryptography (key never accessible to the application in clear-text)
- Possibility to encrypt, with AES-256, any PKA blob encryption key using the device unique secret key DHUK (in the SAES), which makes the PKA encrypted blob usable only on this device
- Software-reset capability
- Repository for cryptographic subsystem tamper event flags

29.3 CCB implementation

The CCB connects the peripherals listed in *Table 249*.

Table 249. Peripherals connected by CCB interconnect

Peripheral	Coupling and chaining feature(1)	Tamper status flag in CCB_SR
RNG	Yes	TAMP_EVT0
SAES	Yes	TAMP_EVT1
PKA	Yes	TAMP_EVT2 (registers + PKA RAM)
		TAMP_EVT3 (PKA operations)
CCB	Yes	TAMP_EVT4
AES	No	TAMP_EVT5
HASH	No	-



1. See *Section 29.4.4* for details.

29.4 CCB functional description

29.4.1 CCB block diagram

Figure 243 shows the CCB block diagram. Peripherals connected to the CCB interconnect, with optional coupling/chaining features, are defined in *Section 29.3*.

Figure 243. CCB block diagram

29.4.2 CCB internal signals

Table 250 describes the relevant internal signals interfacing the CCB peripheral. Signals targeting peripherals connected to the CCB are not listed.

Table 250. CCB internal input/output signals

Signal name	Signal type	Description
hclk	Digital input	Interconnect system clock input
ccb_hclk_en	Digital output	CCB clock request to the RCC
x_hclk_en	Digital output	Peripheral x clock request to the RCC (x = SAES, PKA, or RNG)

29.4.3 CCB reset and clocks
